osmolality (calculated according to McCance, *J. Physiol.*, 1945, 104, 196) 456, range 154 to 928. Animals caught in summer at least 2 miles from fresh water excreted 3 ml. per hr. or less of a highly concentrated urine, mean osmolality 1163. Under laboratory conditions with food and water to appetite the mean osmolality of the urine was 433; after 2 days on diet providing 52 g. metabolic plus free water per 100 g. it was 1528. Eight kangaroos received this dry diet for 2 days and were then given sea water or 3.5 per cent. NaCl solution by stomach tube, after which the osmolality of the urine was similar to that after simple dehydration. Animals were kept in good condition for several days when drinking solutions containing up to 2.5 per cent. NaCl, but they would not drink sea water, and when it was given in large amounts by stomach tube one died.

Temperature regulation in the range 21° to 40° C. with relative humidity 44 to 60 per cent. compared well with that of placental mammals. The animals sweated from the paws and salivated slightly.

It is considered unlikely that *Setonix* drinks sea water; it probably maintains its water balance by conservation and by selecting the most succulent plants available.—D. Duncan.

KLATSKIN, G., KREHL, W. A. and CONN, H. O. The effect of alcohol on the choline requirement. 1. Changes in the rat's liver following prolonged ingestion of alcohol.

KLATSKIN, G. and KREHL, W. A. 2. Incidence of renal necrosis in weanling rats following short term ingestion of alcohol. *J. Exp. Med.*, 1954, 100, 605-614; 615-627. [Dept. Int. Med., Sch. Med., Yale Univ., New Haven, Conn.]

1. Groups of 7 to 15 rats received a basal diet containing, per cent., casein 12, Crisco 20, maize oil 5, sucrose 57.8, cystine 0.2 and salts 5, with vitamins added but not choline. Some groups

received instead of drinking water a 15 per cent. dilution of 95 per cent. ethanol in unrestricted quantity. Pair-fed with rats on the basal diet plus ethanol were groups given supplements of 0.5 per cent. methionine, or 0.5 per cent. choline, or without alcohol, or with the alcohol replaced by an isocaloric amount of sucrose, with or without choline or methionine. The 25 controls received the basal diet to appetite. Survivors were killed after 223 or 226 days.

All rats grew well, but those given alcohol consumed less total energy and gained less weight. The mean intake of 15 per cent. alcohol was 12.5 ml. daily, equivalent to 17 per cent. of the total

N.A. and R., July 1955

energy. Neither alcohol nor extra sucrose produced significantly more liver fat than the basal diet given to appetite, but each produced more than in pair-fed controls on basal diet. This was prevented by choline or methionine.

It is considered that alcohol increases the choline requirement of the rat, but not by augmenting the energy intake.

2. Groups of 50 weanling rats received a basal diet containing, per cent., groundnut meal 30, casein 6, cystine 0.1, sucrose 39.5, lard 19, cod liver oil 1 and salt mixture 4.4, with vitamin B₁, pyridoxine, riboflavin, calcium pantothenate, nicotinic acid, inositol, α -tocopherol, α -tocopherol acetate and 2-methyl-1:4-naphthoquinone. The choline content was 88.8 mg. per 100 g. One group received this diet and alcohol to appetite, another was pair-fed and given sucrose instead of alcohol, another was pair-fed, but without alcohol or sucrose, and the fourth was given the basal diet to appetite. The survivors were killed after 7 to 14 days.

Kidney necrosis was developed in rats given alcohol, and in a few animals in both pair-fed control groups. The addition of 0.08 per cent. choline to the basal diet was enough to prevent kidney damage in all groups.—D. Duncan.

STEVENS, C. M., JOHNSON, C. A. and WATANABE, R. Preparation of *S*-allyl-DL-homocysteine and related compounds and tests of their growth effects in rats. *J. Biol. Chem.*, 1955, **212**, 49-57. [Fulmer Chem. Lab., State Coll. Washington, Pullman.]

DL-Ethionine inhibited growth in rats on a diet low in choline and methionine, but *S*-allyl-DL-homocysteine, the vinyl analogue of methionine, and *S*-*n*-propyl-DL-homocysteine did not. These substances neither maintained bodyweight on a diet deficient in methionine and cystine but adequate in choline, nor inhibited growth when cystine or homocysteine was added. Their sulphoxides and that of *S*-allyl-L-cysteine had similar effects on rats on a diet deficient in cystine.

CONSTANTINIDES, P., CAIRNS, A. and WERNER, A. Antilipemic activity of sulfated polysaccharides. *Arch. internat. Pharmacodyn.*, 1954, **99**, 334-345. [Dept. Anat., Univ. British Columbia, Vancouver.]

Sulphated samples of alginic acid, cellulose, amylopectin, agar, mesquite gum, gum arabic, pectin, amylose, xylan, inulin, glycogen, starch, glucose and glucuronic acid were injected into rats which received at the same time by stomach tube a dose of maize oil. The antilipemic property of the substances was estimated by measurement of

turbidity of the diluted serum 2 hr. later, and also the blood clotting time.

Only the first 5 sulphated polysaccharides significantly reduced blood lipids and their approximate activities, in comparison with heparin expressed as unity, were 1.0, 0.5, 0.2, 0.1 and 0.1. The average clotting times for the minimum antilipemic amounts were 2.3, 3.5, 1.9, 5.7 and 8.5 min., against more than 5 hr. for heparin. Raising the S content of alginic acid from 9.6 to 10.7 per cent. significantly raised the blood clotting time. High sulphation of alginic acid, 19.7, and cellulose, 23.6 per cent. S, destroyed the antilipemic activity. Sulphated alginic acid, cellulose and amylopectin produced some loss of bodyweight in mice. This was least with alginic acid, which, unlike heparin, produced no subcutaneous bleeding.

The data suggested that antilipemic activity decreased with molecular size or with weaker resistance to the acid hydrolysis produced during sulphation of the original material.—A. Hepburn.

WESTERFELD, W. W. and RICHERT, D. A. Acetaldehyde utilization by protein-depleted dogs and rats. *Proc. Soc. Exp. Biol. Med.*, 1954, **87**, 524-526. [Dept. Biochem., Med. Coll. State Univ. New York, Syracuse.]

The rate at which acetaldehyde disappeared from the blood was not altered when dogs were fed on a protein-free diet for 8 weeks, but xanthine oxidase and Mo in the liver decreased. Acetaldehyde was removed more slowly in rats given a protein-free diet for 1 month and xanthine oxidase and Mo decreased considerably. Xanthine oxidase and other enzymes containing Mo were not considered to be of major importance in the metabolism of acetaldehyde *in vivo*.—A. Hepburn.

O'DELL, B. L., STOLZENBERG, S. J., BRUEMMER, J. H. and HOGAN, A. G. The antithyrototoxic factor: its solubilization and relation to intestinal xanthine oxidase. *Arch. Biochem. Biophys.*, 1955, **54**, 232-239. [Dept. Agric. Chem., Univ. Missouri, Columbia.]

The so-called antithyrototoxic factor was assayed with rats which had been fed for a week on a purified casein ration containing 0.15 per cent. iodinated casein, by comparing the growth-promoting effect of the supplement to be tested with that of 10 per cent. liver residue. The supplements tested were aqueous extract of liver, brewer's yeast, wheat germ, soya bean meal and its aqueous extract and insoluble residue, and gelatine. The soya bean meal residue was at least as active in supporting growth of the rats as was liver residue; water extract of liver was moderately active, so

were wheat germ and whole soya bean meal. When liver residue was hydrolysed with several agents all released some of the antithyrototoxic factor, but the hydrolysates with 0.1 N NaOH or NH_4SO_4 were equal to the original residue.

Inactive substances tested were lyxoflavin, thioctic acid, orotic acid, guanine, a mixture of glycine, methionine and arginine, and a mixture of potassium acetate and MgO .

The intestinal xanthine oxidase activity was low on the basal diet of purified casein with or without iodinated casein; without iodinated casein Mo restored activity to normal, but with iodinated casein only to two-thirds of normal. With or without iodinated casein, liver residue restored activity to normal. Mo did not stimulate growth.

ZACCO, M. Studies of glucose intermediaries of rat diaphragm by paper chromatography. *Arch. internat. Pharmacodyn.*, 1954, **99**, 298-313. [John Herr Musser Dept. Res. Med., Univ. Pennsylvania, Philadelphia.] Italian summary.

Diaphragms from normal fasted rats were equilibrated *in vitro* in a medium containing Na_2PO_4 , $NaCl$, $MgCl_2$, and glucose uniformly labelled with ^{14}C . After 45 min. paper autoradiographs were made of the extracts. Glucose, alanine, lactic acid, glycogen and, to a less extent, succinic acid, fumaric acid, pyruvic acid, phosphoglyceraldehyde, dihydroxyacetone phosphate, phosphopyruvic acid and probably 3-phosphoglyceric acid, glucose-1-phosphate, glucose-6-phosphate, fructose-6-phosphate, fructose-1:6-diphosphate and α -ketoglutaric acid were found to be labelled. As a relatively small amount of $^{14}CO_2$ was found, the small activity of pyruvic acid and the intermediates of Krebs' cycle may have been due to transformation of pyruvate to lactic acid and alanine at the expense of oxidation.

The addition of insulin to the medium did not qualitatively affect the radio-active intermediates, but the activity was increased in glycogen and glucose, probably by activated adsorption by the muscle cells of the diaphragm, and especially in the triose phosphates and 3-phosphoglyceric acid. The activities of lactic acid and alanine were only slightly increased.—A. Hepburn.

DIANZANI, M. U. and BIAGGINI, G. C. Alcuni aspetti citochimici dell'ipertrofia renale di compenso. [Cytochemical aspects of compensatory renal hypertrophy.] *Arch. Sci. biol., Bologna*, 1954, **38**, 582-596. [Ist. Patol. Gen., Univ. Genoa.]

Rats weighing 150 to 170 g. were maintained on stock diet with bread and greenstuff. Some had one kidney removed to induce hypertrophy in the remaining kidney. Homogenates were prepared from normal and hypertrophied kidneys and fractionated in the centrifuge.

Hypertrophied kidneys were examined 3, 7 or 25 to 30 days after operation, when they weighed 18.2, 36.7 and 60.5 per cent. more than the kidneys first removed. The N content of homogenates was increased at 3 days, more so at 7, and somewhat less at 30; the increase was especially great in the microsome fraction, and was slight in the mitochondria. The increase in ribonucleic acid was greatest, especially in the supernatant and microsome fractions, at 3 days and then the level tended to return to normal. Deoxyribonucleic acid changed little. Succinoxidase, which is mostly in the mitochondria, increased early and remained high at 30 days, and so did *d*-amino-acid oxidase.

The findings support the theories that nucleic acids control protein synthesis, that the energy necessary for synthesis is provided by oxidative processes, and that the mitochondria are derived from the microsomes.—D. Duncan.

DIANZANI, M. U. and BIAGGINI, G. C. Comportamento della fosforilazione ossidativa nell'ipertrofia renale di compenso. [Oxidative phosphorylation in compensatory renal hyper-

N.A. and R., July 1955

trophy.] *Arch. Sci. biol., Bologna*, 1955, **39**, 72-79. [Ist. Patol. Gen., Univ. Genoa.]

Renal hypertrophy was produced in adult rats fed on diets containing bread and greenstuff, either by removal of one kidney or by ligation of one peduncle. Oxidative phosphorylation was studied in the normal kidneys removed, and later the rats were killed and the other kidneys were studied. The substrates were glutamate, citrate and ketoglutarate, and both homogenates and mitochondrial fractions were used. The results are tabulated.

Phosphate utilisation and oxygen consumption were increased in the hypertrophic kidneys, the P:O ratio remaining constant. In the hypertrophic kidneys with peduncles ligated the utilisation of P fell more than that of oxygen, so the P:O ratio was reduced. The increased oxygen consumption in hypertrophic kidneys began before the increase in nucleic acid and N occurred, and it is concluded that the extra oxygen was used to supply energy for the synthesis of new cytoplasmic materials.—D. Duncan.

FRUNDER, H. and RICHTER, G. Über Änderungen der DPN/DPNH-Konzentrationen in Schnitten normaler und verfetteter Lebern während des Warburg-Versuches. [Changes in the concentrations of DPN and DPNH in sections of normal and fatty livers during Warburg experiments.] *Hoppe-Seyler's Ztschr.*, 1955, **299**, 39-47. [Physiol. Chem. Inst., Univ. Leipzig.] English summary.

The injury to cell and tissue structure involved in the preparation of liver slices causes enzymic destruction of the oxidised (DPN) and reduced (DPNH) diphosphopyridine nucleotides of the live cell. The DPN of the cut tissue is apparently not so well protected from the DPN-ase as it is *in vivo*. After 60 min. of continuous Warburg incubation under aerobic or anaerobic conditions, slices of normal livers contained about 50 per cent., and slices of fatty livers 25 to 30 per cent., of the total DPN and DPNH concentrations found in live tissues. In fatty livers the DPNH was almost entirely lost on incubation. When nicotinamide was added to the medium higher concentrations of DPN were found, but DPNH remained unchanged; this indicates the significance of DPN-ase for the destruction of DPN in cut tissues. Intact livers showed changes fundamentally similar but less far-reaching than those in slices.

EMMELOT, P. and BOSCH, L. The influence of oestrogens on the protein and lipid metabolism of the mouse uterus, studied with acetate- 1-C^{14} . *Rec. Trav. chim. Pays-Bas*, 1954, **73**, 874-877.

Vol. 25, No. 3

[Dept. Biochem., Netherlands Cancer Inst., Amsterdam.]

Ovariectomised mice were given an intraperitoneal injection of 0.1 μg . oestrone, 17 β -oestradiol or oestriol contained in 0.2 ml. ethanolic buffer solution; control ovariectomised animals were injected with buffer alone. The mice were killed 24 hr. later and uterine segments were incubated for 5 to 6 hr. at 37° C. in Krebs Ringer bicarbonate buffer containing $\text{CH}_3^{14}\text{COOK}$. The tissue was then fractionated into proteins, cholesterol and fatty acids and the radio-activity of each fraction was measured.

After injection of the oestrogens the surviving uterine segments showed significantly greater incorporation of ^{14}C into proteins, cholesterol and fatty acids than the control group; the activity was in the order 17 β -oestradiol > oestrone > oestriol (in one experiment oestriol was without effect).—G. A. Garton.

ELIASCH, H., SELLERS, A. L., ROSENFELD, S. and MARMORSTON, J. Protein metabolism in the mammalian kidney. *J. Exp. Med.*, 1955, **101**, 129-134. [Inst. Med. Res., Cedars of Lebanon Hosp., Los Angeles, Calif.]

Significantly higher concentrations of amino-acids and polypeptides were found in the renal vein than in the aorta or the inferior vena cava of the rabbit. The results are consistent with the hypotheses that plasma proteins normally pass the glomerular filter and are re-absorbed and broken down by cells forming the proximal convoluted renal tubule, and that the re-absorbed protein is partly broken down by proteolytic enzymes. It is possible also that the metabolism of cellular proteins of the kidney itself contributes to the amino-acid and peptide content of renal vein blood.—M. B. Richards.

KINNORY, D. S., TAKEDA, Y. and GREENBERG, D. M. Isotope studies on the metabolism of valine. *J. Biol. Chem.*, 1955, **212**, 385-396.

[Dept. Physiol. Chem., Sch. Med., Univ. California, Berkeley.]

After incubation of rat liver homogenates with DL-valine labelled with ^{14}C in the 4, 4' positions, α -ketoisovaleric, isobutyric, β -hydroxyisobutyric and propionic acids were isolated. The same acids were isolated from rat liver after intraperitoneal injection of labelled valine. Carbon atoms 1 and 3 of propionic acid were equally radio-active, but atom 2 was hardly labelled. Incubation of DL-valine-4:4'- ^{14}C with rat kidney homogenate, which cannot oxidise beyond propionic acid, yielded negligible amounts of $^{14}\text{CO}_2$, but the CO_2 obtained from DL-valine-2- ^{14}C was radio-active. The data support the hypothetical catabolic sequence: valine \rightarrow α -ketoisovaleric acid \rightarrow isobutyric acid \rightarrow β -hydroxyisobutyric acid \rightarrow propionic acid.

RUTMAN, J., RUTMAN, R. J. and TARVER, H. Studies on protein synthesis *in vitro*. 5. The effect of diet and fasting on the incorporation of methionine- S^{35} into liver protein. *J. Biol. Chem.*, 1955, **212**, 95-103. [Dept. Physiol. Chem., Sch. Med., Univ. California, Berkeley.]

For previous parts, see Absts. 709, Vol. 17; 736, Vol. 20; *Arch. Biochem. Biophys.*, 1953, **42**, 387.

Liver slices from rats fed on a protein-free diet, a stock diet or diets containing 15 or 45 per cent. casein were incubated with glucose and DL-methionine labelled with ^{35}S . The incorporation of labelled methionine as such into the liver protein was estimated by hydrolysis and precipitation as benzidine sulphate. It was assumed that such protein was synthesised and that labelling was not due to adsorption or an exchange reaction, that normal liver contained 23 per cent. protein and that the protein synthesised contained normal amounts of methionine.

The highest rate of incorporation of methionine was with the 45 per cent. casein diet, which gave twice the rate with the protein-free diet, the lowest. After 1 day's fasting the rate of incorporation into livers from rats fed on diets containing no protein or 15 per cent. casein was higher than before, but on the high-protein diet the rate decreased. The rate of incorporation in all rats after 4 days' fasting was below that in fed rats.—A. Hepburn.

3942

ÅGREN, G., DE VERDIER, C. and GLOMSET, J. A study of the phosphorus-containing proteins of cells. 2. The turnover rate of P^{32} -labelled phosphoserine of the Schneider protein residues of several rat organs. *Acta chem. scand.*, 1954, **8**, 1570-1578. [Inst. Med. Chem., Univ. Uppsala.]

For part 1, see Abst. 69, Vol. 25.

After phosphate labelled with ^{32}P had been injected into rats the Schneider protein residues (see part 1) from liver, kidney, intestine, spleen and heart were separated into 6 fractions by chromatography. By far the largest active fractions were inorganic P and phosphoserine; the others were complex mixtures of peptides. Specific activity of the phosphoserine fraction reached a peak after about 3 hr., mainly in liver and kidney. Further separation of the fractions led to isolation of phosphoserine in a pure state, and its radioactivity during 30 hr. is tabulated.—A. Hepburn.

FELL, H. B. and MELLANBY, E. The biological action of thyroxine on embryonic bones grown in tissue culture. *J. Physiol.*, 1955, **127**, 427-447. [Strangeways Res. Lab., Cambridge.]

Skeletal explants were obtained from the leg- and wing-buds of embryonic chicks 4 to 7 days old. The limb-buds were classified according to the stage of differentiation. Thyroxine was added at the rate of approximately 16 μg . per 100 ml. medium.

The same concentration of added hormone could be ineffective, stimulatory or toxic according to the stage of differentiation of the bone rudiments at the beginning of treatment. The youngest rudiments were stimulated to grow and the cartilage cells matured more quickly than those of the controls. The older explants were more liable to toxic action and grew much more slowly; leg bones were more severely affected than those of the wing, and of the wing bones the humerus was the most susceptible to damage and the radius the most resistant.—B. W. Simpson.

3944

RUDRA, M. N. The effect of selenium on the isolated rabbit intestines. *Indian J. Physiol. Allied Sci.*, 1954, **8**, 155-157. [Dept. Biochem., Darbhanga Med. Coll.]

Se in concentrations of 100 to 500 μg . per 100 ml. reduced the rate of contraction of segments of rabbit jejunum in Ringer Locke solution. The effect was reversible.—D. Duncan.

ALLISON, J. B., WANNEMACHER, R. W. (Jr.), HILF, K., MIGLIARESE, J. F. and CROSSLEY, M. L. Dietary protein and tumor-host relationship in the rat. *J. Nutrition*, 1954, **54**, 593-600. [Bur. Biol. Res., Rutgers Univ., New Brunswick, N.J.]

Male rats were hosts for the sarcoma R-1 (Babson, *Cancer Res.*, 1954, **14**, 89) and its induction period was taken as the time in which it reached a weight of 0.5 g. The effect of N, N', N'' triethylenephosphoramidate was studied.

A diet with 12 per cent. casein gave the shortest induction period. Adding methionine to the diet or increasing its casein content lengthened the induction period and favoured carcass development. When the drug was injected intraperitoneally, 1 mg. per kg. bodyweight daily, the rate of growth of both tumour and carcass was reduced and the chance of survival increased.—D. Harvey.

3947

FISCHER, W. Durch Buttergelb erzeugte Tumoren. [Tumours produced by butter yellow.] *Arch.*

Geschwulstforsch., 1954, **7**, 301-320. [Inst. Mikrobiol., Jena.]

Five white rats which had received from 20 to 30 mg. butter yellow almost daily in their diet for between 200 and 300 days, total amounts from 1.386 to 2.282 g., developed large liver tumours, which are described in great detail, with photomicrographs. The tumours could be transferred to other rats.

None of 17 mice and only 1 of 10 hamsters given butter yellow have developed tumours so far. The hamster had on the average 30 mg. butter yellow for about 100 days, 2.7 g. in all. The tumour, which is described, was transferred to other hamsters.

The findings are discussed with reference to the possible connection between liver cirrhosis and primary liver cancer in man.—W. M. Deans.

HAHN, L. Doubling the birthweight: a study of the rate of growth during the first five months of life. *Med. Officer*, 1955, **93**, 75-77. [Dept. Maternity and Child Welfare, Leicester.]

The subjects were healthy infants, 171 boys and 149 girls, attending infant welfare centres in Leicester in 1952 and 1953; about two-thirds were breast fed for at least 2 months.

Mean birthweights were 7.6, s. d. ± 1.1 lb. (3.454 ± 0.5 kg.) for boys and 7.2 ± 0.98 lb. (3.273 ± 0.445 kg.) for girls. Time taken to double the birthweight ranged from 8 to 31 weeks, mean 17.98 ± 5.1 weeks for boys and 18.7 ± 4.12 weeks for girls. It increased with birthweight, the coefficients of correlation being $r = +0.64$ for boys and $r = +0.69$ for girls.

Average daily gain for girls was almost constant

Vol. 26, No. 3

for all birthweights at about 0.87 oz. (24.7 g.); this was also the value for boys of birthweight over 8 lb., but lighter boys put on weight more quickly. Hence a linear regression equation could be used to predict time to double birthweight from birthweight for girls but not for boys. Three simple formulae which can serve as a rough criterion of satisfactory growth are put forward. In the author's opinion, the statement that a baby doubles its birthweight at 5 or 6 months is misleading and should be dropped from textbooks.

W. M. Deans.

3951

THOMSON, J. Height and weight at three years. *Health Bull., Dept. Health Scot.*, 1955, **13**, 16-17.

Mean weights and crown-heel and crown-rump lengths are given for healthy Edinburgh children aged 3 years, 109 boys and 101 girls. Comparison with Edinburgh child welfare clinic data of 30 years ago showed a rise of about $2\frac{1}{2}$ lb. in weight and 1.27 inches in length, of which 2 lb. and 0.9 in. are accounted for by the first year of life (Abst. 1956, Vol. 25). Body length was significantly correlated with height of mother.—W. M. Deans.

3952

ACHESON, R. M. and HEWITT, D. **Physical development in the English and the American pre-school child. A comparison between findings in the Oxford and the Brush Foundation Surveys.** *Human Biol.*, 1954, **26**, 343-356. [Social Med. Unit, Univ. Oxford.]

The 500 children whose development was studied from birth to 5 years of age in the Oxford Survey were from different economic levels. The Brush study of Cleveland children aimed at describing the process of development in an optimum environment.

Data on height and skeletal maturity according to Todd's standard of boys and girls in both surveys are tabulated according to calendar age. Increases in height and skeletal maturity between the ages of 2 and 5 years and increases in height of children in the same phase of skeletal maturity are tabulated also. On the average, the Oxford children were shorter and skeletally less mature than the Cleveland children. The difference in maturity was slightly less for girls than for boys. The differences were similar to those found between different economic strata within the Oxford Survey.—F. C. Aitken.

3953

DREIZEN, S., CURRIE, C., GILLEY, E. J. and SPIES, T. D. **The effect of nutritive failure on the growth patterns of white children in Alabama.** *Child Development*, 1953, **24**, 189-202. [Dept. Nutrit. Metabol., Northwestern Univ., Chicago, Ill.]

In continuation of previous studies of "chronic nutritive failure" in children (see Abst. 1012, Vol. 18) mean heights in inches and weights in lb. and standard deviations are tabulated at 3-month intervals from 3 years to 15 years 9 months for test groups of 267 boys and 294 girls with chronic nutritive failure and control groups of 1182 boys and 1222 girls without evidence of nutritive failure. The results are plotted on the Wetzel grid. All the children were of Anglo-Saxon extraction and lived in or near Birmingham, Alabama.

At almost every age the mean height of the control children exceeded that of the children with nutritive failure, though not by more than one standard deviation. Differences in mean weights generally exceeded one standard deviation. Both sets of differences tended to be greater and more persistent for boys than for girls. The mean height of the boys with nutritive failure at 15 years 6 months was 64.5 in., a height reached by the control boys at 14 years; that of the girls with nutritive failure at 15 years 3 months was 62.7 in., reached by the control girls at 14 years. Nevertheless, individual values overlapped to some

extent and it is concluded that though "failure to reach the average height, weight or speed of growth for a particular sex at a particular age is suggestive of poor quality growth due to faulty nutrition, corroborative clinical evidence is essential in the final evaluation of the nutritional status of the child."—W. M. Deans.

MEREDITH, H. V. and MEREDITH, E. M. **The body size and form of present-day white elementary school children residing in west-central Oregon.** *Child Development*, 1953, **24**, 83-102. [State Univ. Iowa, Iowa City.]

This forms the concluding section of a study of white children in Oregon in 1950 to 1952; for previous parts see *Growth*, 1951, **15**, 39; *Absts.* 978, Vol. 22, 715, Vol. 23 and Title 4976, Vol. 24.

Mean, standard error, standard deviation and 5th, 10th, 30th, 70th, 90th and 95th percentiles are tabulated for weight, height and 9 other body measurements, in kg. and cm., for groups each of over 200 boys of 7 and 9 and of about 150 girls of 7, 9 and 11 years, mainly of northwest-European descent, attending public elementary schools in Eugene and 2 other places in Oregon.

The children were taller than Californian children of the nineties (Boas, *Science*, 1895, **1**, 402) by 2½ to 3 inches, and heavier by 7 lb. at age 7 and by 10 to 15 lb. at ages 10 and 11, and were significantly taller and heavier than children in California, Utah, Texas, Maryland, Virginia and Minnesota in the thirties and than English children in 1948, according to Sutcliffe and Canham, "The heights and weights of boys and girls" (John Murray, 1950).

Tables are given for 5 ratios of body measurements which indicate slenderness or stockiness and the relative dimensions of the upper and lower halves of the body. Examples are given of the use of the tables to indicate body form, and age changes and sex differences in body form are discussed.—W. M. Deans.

3955

EPPRIGHT, E. S. and SIDWELL, V. D. **Physical measurements of Iowa school children.** *J. Nutrition*, 1954, **54**, 543-556. [Iowa Agric. Exp. Stat., Ames.]

Measurements were made of height, weight, chest breadth, hip width and leg girth on 1200 Iowa schoolchildren aged from 6 to 18 years and chosen at random throughout the State. Nutrient intakes and nutritional status were studied concurrently (see *Absts.* 4045-4047).

The means at successive ages agreed closely with those obtained for Iowa City children. Mean weights at most ages tended to be greater than those obtained in Iowa 10 years earlier, but mean

heights were similar. By most standards of comparison fewer girls than boys were "normal"; at 12, fewest children were within the normal range. More girls than boys were overweight, and more older girls than younger ones. Major differences in mean body measurements of children of successive ages are compared with mean nutrient intakes. Increments in mean bodyweight from year to year were irregular for boys and regular for girls. During adolescence mean weight and height of girls tended to increase although the average nutrient intake failed to increase or, in some instances, notably Ca, decreased with age.

YANO, K. An analytical study on the annual physical growth of school children in Japan. *Kurume Med. J.*, 1954, 1, 109-112. [Dept. Environmental Hyg., Sch. Med., Kurume Univ., Kurume-shi, Japan.]

The growth of Japanese children was seriously affected by the war [no data are given]. The rate of relative increase in height and weight (see Abst. 965, Vol. 25) was calculated for 3 sets of children grouped according to the year of their entering primary schools, 1900 to 1911, 1916 to 1930 and 1941 to 1947. The ages at which these rates were at their maximum were, for heights: boys, 14-1, 13-7, 14-7 and girls 12-3, 11-9, 12-0 years, and for weights: boys 14-2, 13-9, 14-7 and girls 12-5, 12-3, 12-8 years. It is concluded that the children in the second group grew up under conditions more favourable than those which existed during war time for the third group.—D. Harvey.

TYLER, F. T. Organismic growth: P-technique in the analysis of longitudinal growth data. *Child Development*, 1954, 25, 83-90. [Univ. California, Berkeley.]

Until recently most studies of growth have depended on cross-sectional data obtained from

groups of subjects of different ages more than on longitudinal data from the same subjects at different times. Statistical methods for longitudinal data have not been extensively investigated. An example is given of the application to this purpose of factor analysis, originally developed in connection with intelligence tests. The data consist of the rates of increment, over 14 successive intervals of about 6 months each, of 12 physical measurements made on a single subject in a study of adolescent growth. Measures are obtained of the correlation over time between each pair of rates of increment, and 3 factors are extracted from the correlation matrices obtained. For the most part the factor loadings are not significant, indicating that there was not a high degree of unity in the rates of growth of the 12 physical characteristics of the adolescent boy in question.

DUPERTUIS, C. W. and MICHAEL, N. B. Comparison of growth in height and weight between ectomorphic and mesomorphic boys. *Child Development*, 1953, 24, 203-214. [Sch. Med., W. Reserve Univ., Cleveland, Ohio.]

From 125 young men, former subjects of the Brush Foundation Study of Cleveland children, used for a somatotype study, 26 ectomorphic, i.e., "characterised by linearity and delicacy of body structure", and 28 mesomorphic, i.e., "with pronounced development and ruggedness of structure", were selected for a retrospective study of their growth. For both groups the mean age was about 21 years but the range was from 16 to 30; the mean height of the ectomorphs was then 2-3 in. greater than that of the mesomorphs, and their

mean weight was 26.7 lb. less. Curves of mean height and weight showed that the ectomorphs were taller than the mesomorphs after 4 years of age, but not significantly so, and significantly lighter at almost every age, and they had a significantly higher ratio of height : cube root of weight, which began to level off at about 11 years as against 9 for the mesomorphs. At every age mesomorphs had achieved a significantly higher percentage of their final adult stature than ectomorphs.

It is concluded that the type of body build tends to persist throughout childhood and adolescence and that in view of the differences in growth pattern, further studies of the growth of children of different body types are required.

3962

NICHOLSON, A. B. and HANLEY, C. Indices of physiological maturity: derivation and interrelationships. *Child Development*, 1953, 24, 3-38. [Inst. Child Welfare, Univ. California.]

The data for this statistical examination of indices of maturity came from a longitudinal study up to age 18 of about 160 boys and girls representative of those born in Berkeley, California in 1928 and 1929.

Indices of maturity defined and considered for both sexes are age at reaching maximum growth (i.e., chronological age at which the largest increment in height occurs), skeletal development, percentage of mature height, age of walking; for girls, age at menarche, development of breasts, development of pubic hair; for boys, amount and pattern of pubic hair and size of genitalia.

A factorial analysis by Spearman's method of the intercorrelations of these indices is made, except age of walking, which was not correlated with the others. For each sex this yielded a general factor which accounted for well over half the variance of each index. In both sexes the best single measure of maturity was the age of reaching 90 per cent. of mature height. Other good indices, which could be used in the absence of adequate longitudinal data, were, for girls, age of reaching skeletal age 12.75 (Todd's standard), stages of development of pubic hair and breasts, and age at menarche; for boys, age of reaching skeletal age 11.25, age of reaching skeletal age 14.75, and stages of development of genitalia.

Multiple regression equations were used to obtain an overall maturity score for individuals.

Some of the findings are presented in tables and histograms. The mean age of reaching 90 per cent. of mature height was for boys 13.7 ± 1.04 (standard deviation), for girls 11.4 ± 0.78 years. The mean age of maximum growth was 13.77 ± 1.17 for boys and 11.51 ± 1.13 for girls. Sexual development in boys began to appear at mean age 11.8 ± 1 and reached adult stage at mean age

15.2 ± 1 . For breast development in girls the corresponding ages were 10.6 ± 1.2 and 13.9 ± 0.9 . The mean age of menarche was 12.8 ± 1.1 years.

3963

PENDSE, G. S. Refraction and body-growth. *Indian Med. Res. Mem.* No. 38, August 1954, pp. vii + 94. [Eye Clin., Poona 2.]

About a quarter of this memoir consists of introductory matter on problems of refraction and body growth and on elementary statistical methods.

The subjects belonged to 2 communities, an "advanced" one, middle-class, mostly professional, people belonging to 2 endogamous Brahmin sub-castes, vegetarian but not rigidly so, living in a particular part of Poona, and a "backward" one, of several "untouchable" sub-castes, menially employed in the city, non-vegetarian but with a low standard of living, and anthropomorphically different from the Brahmins.

Mean heights (in.) and weights (lb.) are given in tables for unselected boys (497) and girls (685) aged from 6 to 18 years of the advanced community. Girls were taller than boys from 8 to 14 but the difference was significant only at ages 10 and 11. Weight was not studied closely, as it turned out not to be connected with refraction. Pubescence, judged by pubic hair, was studied in 584 unselected boys of this community aged from 7 to 16; at ages 12, 13 and 14 the more mature boys were taller than the less mature. At ages 6 to 12 the untouchables [number not stated] were on the average 1 to 2 in. taller than the Brahmins [whether the comparison is for both sexes together or only for males is not clear], the differences being significant at the 1 per cent. level.

The difference in mean refraction (measured under atropine by one observer) between 590 Brahmins and 645 untouchables aged from 6 to 12 was highly significant; the untouchables were more inclined to be myopic, contrary to the idea formerly prevalent that myopia is associated with educational stress. A sub-group of the Brahmins, believed on the basis of blood-group studies to be genetically distinct, did not differ in refraction from the others.

Results for 1182 Brahmins, namely, the 590 between 6 and 12 already referred to (162 boys and 428 girls) and 592 between 12 and 18 (335 boys and 257 girls) showed a general trend towards myopia with increasing age. There was no significant sex difference except at age 12, when the girls were more myopic than the boys. The 645 untouchables between 6 and 12 showed the same age trend. These groups did not include subjects with myopia exceeding - 6 D (dioptries).

In the group of Brahmins between 6 and 12 the children above average height were more myopic than those below, but this effect disappeared when

N.A. and R., July 1955

the effect of age was eliminated. But 25 subjects between 12 and 18, with myopia exceeding - 6 D but without degenerative change, were significantly tall for their age. High myopia seemed to be associated with rapid puberty changes, though biochemical studies showed no difference in serum inorganic P, serum Ca or plasma protein. Among the younger children those with high myopia had significantly low Hb and serum Ca values compared with non-myopic children, but there was nothing to show whether the defect was metabolic or nutritional in origin.—W. M. Deans.

ROSENBAUM, S. **Heights and weights of the Army intake, 1951.** *J. Roy. Statistical Soc., Ser. A (Gen.)*, 1954, **117**, 331-347.

An analysis is made of height, weight and age data obtained in 1951, for 134,317 men who joined the army in that year, the measurements being recorded during the first days of a man's service. Details are recorded separately for National Servicemen and Regular Army recruits. The latter ranged in age from 17 to 49 and most of the former were 18 years old and none was over 24. The older National Servicemen constitute a selected group, having had their call-up deferred for educational or other reasons. The only earlier results with which comparisons can properly be made relate to recruits aged from 20 to 21 in 1939. Compared with the Regular recruits of 1951 of similar age the former were on the average half an inch shorter and 6 lb. lighter. On comparing recruits of the same year of birth, the mean increase in weight between 1939 and 1951 was found to be 12 lb.

Regression analyses were made of weight on height and of height on weight, and are used to produce standard tables of weight for given age and height. Over the groups from 20 to 40 years old there is a steady increase in weight, totalling 8 lb., and a decrease in height, totalling half an inch. Supplementary measurements on a random sample of the National Servicemen showed that during the 3 months of initial training in the army their rate of gain in weight was from 3 to 4 times as great as in the preceding 2 months.

WEIKEL, J. H., BONNER, J. F. and NEUMAN, W. F. **Skeletal growth of the rat.** *Proc. Soc. Exp. Biol. Med.*, 1955, **88**, 122-124. [Div. Pharmacol., Dept. Radiation Biol., Sch. Med. Dent., Univ. Rochester, N.Y.]

Rats aged from 15 to 170 days, 225 in all, were killed and skeletons were ashed, individual bones of the limbs, skull and 4 lumbar vertebrae from the males being ashed separately. Skeletal weight is presented graphically as a function of bodyweight

Vol. 25, No. 3

on a logarithmic scale; the function relating the 2 variables was the same as that for a colony of rats described earlier (Abst. 3207, Vol. 16). Such variations occurred among skeletal components as to make impracticable the use of any one bone as quantitatively representative of the skeleton. An equation for comparing the growth rates of the different bones, which requires only the weights at 2 ages after weaning, is proposed.—G. F. Garton.

HUMPHREYS, R. C. **An analysis of the maternal and foetal weight factors in normal pregnancy.** *J. Obstet. Gynaecol. Brit. Empire*, 1954, **61**, 764-771.

The analysis was based on the records of 1000 normal mothers, booked hospital patients, who were delivered during 1944. The criteria of normality were that mothers should be free from pre-existing disease, should not develop toxæmia of pregnancy, and should produce normal live babies within 20 days of the expected date. They were also selected on grounds of first attendance at the antenatal clinic at or before the twelfth week of pregnancy and last attendance within 7 days of delivery. The average weight gain in the series was 13.7 lb., S.D. 5.71, in the second trimester and 10.6 lb., S.D. 5.68, in the third. It is assumed that the gain in the first trimester is negligible. Primiparae gained slightly more than multiparae and younger women more than older. There was evidence, not reaching a statistically significant level, that weight gains were less as weight at 12 weeks was greater. Greater weight gains were associated with greater birthweights, but no relation with duration of labour was found.

A. M. Thomson.

3967

SIMPSON, A. S. **The significance of haemoglobin estimations in pregnancy.** *J. Obstet. Gynaecol. Brit. Empire*, 1954, **61**, 807-810. [Ashton-under-Lyne, Lancs.]

Hb and haematocrit measurements were made at intervals during pregnancy on 216 women, and showed the expected decline which was attributed to haemodilution of pregnancy. On the other hand, mean cell Hb concentrations (M.C.H.C.) calculated from the data remained fairly stable, and it is argued that only the M.C.H.C. can be used reliably to indicate the presence of anaemia during pregnancy.—A. M. Thomson.

3968

BROWN, T. **Electrophoretic analysis of serum proteins in pregnancy: a preliminary study.** *J. Obstet. Gynaecol. Brit. Empire*, 1954, **61**,

781-787. [Dept. Res., Royal Maternity Hosp., Glasgow.]

Sera from 35 women, 5 non-pregnant and 10 in each trimester of pregnancy, were quantitatively analysed by paper electrophoresis. Total serum proteins and albumin rose slightly above the non-pregnant levels in the first trimester, then progressively declined by 11.5 and 32 per cent. from early to late pregnancy. Total globulin and the α_1 , α_2 and β -fractions correspondingly increased by 20, 7, 66 and 37.5 per cent. and γ -globulin decreased by 22 per cent. The albumin:globulin ratio fell steadily from 1.5 in the non-pregnant women to 0.8 in late pregnancy.—A. Hepburn.

3969

PFÄU, P. Die Serumverhältnisse während der normalen und gestörten Schwangerschaft. (Papierelktrophoretische Untersuchungen.) [Serum ratios during normal and disordered pregnancy. (Studies with paper electrophoresis.)] *Arch. Gynäkol.*, 1954-55, 185, 188-207. [Frauenklin., Univ. Heidelberg.]

A study was made of the agreement between estimates of serum albumin and α , β , and γ -globulin by paper electrophoresis made in duplicate at the same time, with different electrophoresis chambers and at intervals of 1, 2, 4 and 8 days after the blood was taken. A comparison was also made between the methods of Grassmann and Antweiler with 1 normal and 12 pathological sera. From these the conclusion is that results got by different methods are comparable only within limits.

Next, results for total protein, by the Zeiss immersion refractometer, and its fractions are presented for 20 healthy non-pregnant women and 10 pregnant women in each month of pregnancy from the first to the tenth. The means for the normal women were: total 7.5 \pm 0.09 g. per 100 ml. and, per cent., albumin 63.8, α -globulin 10.8, β -globulin 11.5 and γ -globulin 15.0. The means for the pregnant women, for the first and last months, in the same order were: 7.4 \pm 0.11 and 6.9 \pm 0.13 g. and 56.2 and 51.1; 14.4 and 18.1; 10.2 and 14.0; and 19.4 and 16.9 per cent. On the assumption that plasma volume is 2236 ml. in the non-pregnant and 3033 ml. in the pregnant woman, increases in total albumin and in all globulins occur. Mean data are given for women [no number stated] in the eleventh and twelfth months as total protein 7.0 \pm 0.88 g. and fractions 50.5, 18.3, 14.3 and 17.6 per cent.

Data are presented also for 20 patients with hyperemesis, within normal limits, and 48 with toxæmia in later pregnancy (one eclamptic), which are summed up as showing a fall of total albumin and a greater than normal rise of total globulins.—I. Leitch.

3970

TATUM, H. J. Compartmental distribution and shift of water and electrolytes in pre-eclampsia. 2. A comparison of the effects of isotonic and hypertonic glucose when administered intravenously to patients with pre-eclampsia. *Amer. J. Obstet. Gynecol.*, 1955, 69, 415-424. [Dept. Obstet. Gynaecol., Sch. Med., Louisiana State Univ., New Orleans.]

For part 1 see Abst. 868, Vol. 25.

A litre of 5 or 20 per cent. glucose solution was infused intravenously in 20 min. into normal pregnant and pre-eclamptic patients. Packed cell volumes (P.C.V.) and serum Na, K and Cl were estimated immediately before and 10 min. after the infusion and again one hour later. Pre-infusion plasma volumes were estimated by a dye method, and the changes consequent on infusion were calculated from the P.C.V. and electrolyte changes and the urine output.

In all groups, glucose infusion led to transient haemodilution. With 5 per cent. glucose there was a net gain of body water, with evidence of retention in the extravascular space in pre-eclampsia. Hypertonic glucose produced an output of urine in pre-eclampsia equal to or slightly greater than the volume of fluid administered. Neither 5 nor 20 per cent. solution significantly affected Na retention or excretion.

A. M. Thomson.

3971

SEITCHIK, J. and ALPER, C. The body compartments of normal pregnant, edematous pregnant, and pre-eclamptic women. *Amer. J. Obstet. Gynecol.*, 1954, 68, 1540-1545. [Div. Women, Hahnemann Med. Coll., Philadelphia, Pa.]

Antipyrine and mannitol space were measured in 4 non-pregnant, 4 normal pregnant, 8 pre-eclamptic, and 3 oedematous pregnant women without pre-eclampsia. From the data a number of calculations are made which, if the assumptions on which they are based are correct, indicate that extracellular fluid increases in normal pregnancy proportionately to the increase in lean body tissue, i.e., the ratio cell-mass:extracellular fluid remains relatively constant. In untreated pre-eclampsia and in pregnant women with oedema the ratio is reduced, indicating the presence of excess extracellular fluid. Different results reported in the literature, based on estimation of extracellular fluid volume by the inulin space method, are criticised on technical grounds.—A. M. Thomson.

3972

DA CUNHA, D. P. Phosphatase et grossesse. [Phosphatase and pregnancy.] *Arch. portugaises Sci. biol.*, 1952-53, 11, 1-2. [Inst. Rocha Cabral, Lisbon.]

N.A. and R., July 1955

Alkaline phosphatase values did not differ in the serum in groups of 8 women in the last months of pregnancy, in labour, and suffering from eclampsia.—E. M. Hume.

3973

WÖHLER, F. Zur Physiologie und Pathologie des Speichereisens. 3. Über den intermediären Eisenstoffwechsel der Plazenta. [Physiology and pathology of storage of iron. 3. Intermediary iron metabolism in the placenta.] *Deutsch. med. Wochenschr.*, 1955, **80**, 30-32; 41; 49. [Med. Klin., Univ. Freiburg i. Br.]

For previous parts see Titles 4099, Vol. 24; 2364, Vol. 25.

Experiments on rabbits in late pregnancy given labelled ferrous sulphate intravenously suggested that uptake of Fe from maternal plasma is by way of ferritin in the chorionsyncytium or chorionic epithelium. Very large injections of *ferrum vitis* into 3 other rabbits showed that the placenta did not block the absorption of Fe.

Preliminary studies of human placentas *in vitro* showed that about 21 mg. ferritin per cent. was present in 3 placentas from healthy pregnancies; in 7 from disturbed pregnancy it ranged from 13 to over 33 mg. per cent. In all the percentage of Fe in the ferritin was from 21 to 23 per cent.

W. M. Deans.

3974

FÖLMEIER, W. Wachstumsfördernde Stoffe in der Placenta. [Growth-promoting substances in the placenta.] *Arch. Gynäkol.*, 1954-55, **185**, 179-187. [Frauenklin., Univ. Frankfurt a.M.]

Placentas were obtained at operations on women in early and in late pregnancy, in the first 4 months and in the eighth to tenth months, respectively. Dried powdered placenta was added to the water in which were frog tadpoles 10 days old and the growth of the tadpoles was studied for 24 days. With early and late placenta, but especially the latter, growth of the tadpoles was greater than that of normal controls.

A water-soluble preparation of chorionic gonadotropin and one of follicle-stimulating hormone from pregnant mare's serum also stimulated growth of tadpoles, but one of corpus luteum hormone did not. Extracts from late placentas were separated into 3 fractions; in the fraction which had the greatest effect on the growth of tadpoles neither chorionic gonadotropin nor follicular hormone could be identified. It is concluded that placenta contains another substance which promotes growth in embryonic tissues.—D. Duncan.

AJELLO, P. and LOMBARDO, N. L'influenza delle sostanze gonadotrope sulla ovulazione della capra siciliana. [Effect of gonadotropic sub-

Vol. 25, No. 3

stances on ovulation in the Sicilian goat.]

Zootec. Vet., 1955, **10**, 2-12. [Ist. Ostet. Vet., Univ. Messina.] English summary.

Ovulation was induced in 37 out of 41 Sicilian goats by a single intramuscular injection of gonadotropic substances, of either the follicle-stimulating or the luteinising type. Ovulation was generally preceded by oestrus, and occurred immediately when the treatment was given in the normal breeding season, or later when it was given out of season. The rate of ovulation could not be increased above the normal.—T. D. Bell.

ROSENFELD, I. and BEATH, O. A. Effect of selenium on reproduction in rats. *Proc. Soc. Exp. Biol. Med.*, 1954, **87**, 295-297. [Dept. Agric. Res. Chem., Univ. Wyoming, Laramie.]

Groups of 5 pregnant female rats were fed on Purina chow, and some of them received 1.5, 2.5 or 7.5 p.p.m. Se as potassium selenate in the drinking water. Experiments lasted a year and each rat was mated 5 times.

Rats given the 2 lower concentrations of Se had normal litters and reared them; second generation rats had normal litters, but the number of young reared fell by about half.

Rats which were first given 7.5 p.p.m. Se in the water 5 to 8 days before parturition gave birth to normal litters but reared only 13 per cent. of the young. They failed to conceive again when mated with males given Se. The young rats of the first litters, continued on the high Se intake, grew slowly and failed to reproduce. Females given Se and mated with normal males failed to reproduce, but normal females mated with males given Se produced and reared normal litters.—D. Duncan.

3978

MELAMPY, R. M. and COVAZOS, L. F. Comparative study of lipids in vertebrate testes. *Proc. Soc. Exp. Biol. Med.*, 1954, **87**, 297-303. [Iowa Agric. Exp. Stat., Iowa State Coll., Ames.]

Testicular tissue was prepared for histological examination from sexually mature bulls, rams, boars, rats, guineapigs, cocks, horned lizards (*Phrynosoma cornutus*), grass frogs (*Rana pipiens*) and bluegill fish (*Lepomis macrochirus*).

Sudan dyes revealed the presence of lipids in the interstitial cell cytoplasm, basement membrane, cytoplasm of the Sertoli cells, spermatogonia,

spermatocytes and spermatids of each species except the bluegill fish. In that species lipids were present in the germ cells and the interlobular connective tissue sheath. Other stains suggested the presence of ketosteroids in the Leydig cells of all the species examined except boar, cock and fish. Phospholipins were detected in the testicular cells of all species examined; bluegill fish testes were not examined.

It is suggested that the similarity of the patterns of lipid distribution indicates a structural and metabolic importance in spermatogenesis.

G. A. Garton.

3979

McPHERSON, E. A. **Artificially induced lactation in sheep.** *Vet. Rec.*, 1955, 67, 200-202. [Dept. Vet. Med., Royal (Dick) Sch. Vet. Studies, Univ. Edinburgh.]

Lactation was induced in ewes by implantation or intramuscular or subcutaneous injection of stilboestrol, and they then reared healthy orphan lambs. Implantation of a single dose of 105 mg. gave udder development and milk secretion within 2 to 5 days. In 2 sheep an intramuscular injection of 5 mg. was given on the fifth day to hasten development. Daily intramuscular injections of 4 mg. for 15 days were equally successful, except that the development took longer. Forty mg. by subcutaneous injection in one dose gave quicker results, and the ewes produced more milk than the lambs required. In animals for which no lamb was available milk flow continued for 6 weeks, without any sign of mastitis. In the following season the ewes, which had been barren for 2 years, reproduced normally.—T. D. Bell.

TURNER, H. G. **Changes in capacity of the udder of the dairy cow during the course of lactation.** *Austral. J. Agric. Res.*, 1955, 6, 145-160. [Div. Animal Health Prod., C.S.I.R.O., Animal Health Res. Lab., Melbourne.]

The udder capacities of 7 cows were studied in a series of observations with long and short intervals between milkings, at arbitrary intervals during lactation. The udders were emptied with the aid of injections of posterior pituitary extract at the beginning and end, and intramammary pressure was measured by a specially designed tympanometer applied to the surface of the udder.

When yields were plotted against intervals between milkings it was found that no significant inhibition of secretion occurred before 20 hr. Maximum yields were attained after intervals of 35 hr. It was concluded that udder capacity does not remain constant during lactation, but declines in proportion to the decline in daily milk yield.

Intramammary pressure plotted against the amount of milk in the udder at the time of each

reading showed that the maximum pressure attainable by allowing the udder to fill with milk declines with advancing lactation. Milk secretion was inhibited at a lower pressure in late lactation. The physiological implications of these results are discussed in detail.—J. N. Aitken.

3981

WRIGHT, W. E., CHRISTIAN, J. E. and ANDREWS, F. N. **The mammary elimination of radioiodine.** *J. Dairy Sci.*, 1955, 38, 131-136. [Sch. Pharm., Purdue Univ., Lafayette, Ind.]

Iodocasein labelled with ^{131}I and free of iodide was given by mouth to a lactating rabbit. Monoiodotyrosine, diiodotyrosine and iodide were detected in the milk, but no thyroxine.

Two lactating goats were given by mouth 1.5 g. radio-active iodocasein per 100 lb. bodyweight and were milked every 12 hr.; chromatograms of skimmed milk samples from the first 10 collections were prepared. Of the dose administered 15.5 per cent. was found in the milk, but no organic iodine compound. In 4 other experiments in which radio-active NaI was given to lactating goats, about half was eliminated in the milk as iodide. In one experiment the excretion of a dose of Na^{131}I in the milk, urine and faeces was 45.3, 40.7 and 2.3 per cent.—B. W. Simpson.

3982

SCHULTZE, M. O. **Weight increments of suckling rats as affected by litter size and maternal diet.** *J. Nutrition*, 1954, 54, 453-460. [Dept. Agric. Biochem., Univ. Minnesota Inst. Agric., St. Paul.]

Mother rats received diets of yellow maize, sucrose and casein or rolled oats and casein. They were allowed to nurse their entire litters and only data relating to litters in which none of the young died are presented. For each diet, weight increments from birth to 16 days of age per rat and per litter are tabulated for litters of 1 to 14 young. With increasing number of young in the litter, weight increment per rat decreased and weight increment per litter increased. Only when litters contained 7 or more young did the superiority of the rolled oats and casein diet become apparent.

F. C. Aitken.

REPRODUCTION : BIRDS

3983

THIELKE, O. W. (with GOWIN, E.) **Über die Neubildung von Cholin-plasmaplogen im bebrüteten Hühnerei. [Formation of choline-plasmaplogen in the incubated hen's egg.]** *Hoppe-Seyler's Ztschr.*, 1955, 299, 151-155. [Med. Klin., Justus Liebig-Hochsch., Giessen.] English summary.

N.A. and R., July 1955

In yolks of 5 infertile hen eggs most of the plasmalogen was in the choline phosphatide fraction and in 6 fertile eggs incubated for 11 days there was an increase of about 3 times in the plasmalogen in this fraction, from 0.16 to 0.48 per cent. The small amount of plasmalogen in the phosphatide-poor fraction did not increase much.

Plasmalogen is thought to be formed from ester phosphatide.—D. Duncan.

3984

NOZAKI, H., HORII, S. and TAKEI, Y. [Utilisation of shell Ca by chick embryo.] *Bull. Nat. Inst. Agric. Sci., Japan* [G], 1954, No. 9, 89-95. In Japanese: English summary.

⁴⁵Ca was administered by mouth to 6 laying hens; the first 2 eggs subsequently laid by each were incubated and changes in the distribution of ⁴⁵Ca were estimated on the fifth, twelfth and eighteenth days and at hatching.

During incubation the shell lost about 150 mg. Ca. In the early stages of embryonic development the Ca was derived mainly from the yolk and white. In the middle stages the Ca of the amniotic and allantoic fluids was derived mainly from the yolk. In the last half of incubation more than half the Ca in the embryo came from the shell, one-quarter from the yolk and the rest from the white. In the final stage yolk was the main supply of Ca to the embryo, the yolk receiving a considerable supply of Ca from the shell.—J. S. Thomson.

GILLUM, H. L. and MORGAN, A. F. (with JEROME, D. W., VOTAW, M. H. and SNOWDEN, M.) Nutritional status of the aging. 1. Hemoglobin levels, packed cell volumes and sedimentation rates of 577 normal men and women over 50 years of age.

GILLUM, H. L., MORGAN, A. F. and WILLIAMS, R. I. 2. Blood glucose levels. *J. Nutrition*, 1955, 55, 265-288; 289-303. [Dept. Home Econ., Univ. California, Berkeley.]

1. Physical examinations, medical and dietary histories, 7-day diet records and urine analyses were made on 280 men and 297 women over 50 years of age in San Mateo County, California. More than 80 per cent. lived in comfortable middle-class circumstances and all, except 47 who lived in a county home, lived in their own homes.

The average Hb value of men living in their own

homes was 14.5 ± 0.3 g. per 100 ml. blood, compared with 13.4 ± 0.3 for the women. After the age of 75 both values declined and the difference between men and women was not significant. The packed cell volume of men living in their own homes was on the average 47.1 ± 0.7 per cent. and that of women 44.6 ± 0.5 ; the mean corpuscular Hb was 31 and 30 per cent. Eighty-four per cent. of the men and 52 per cent. of the women had sedimentation rates of 0 to 20 mm. per hr. and 16 per cent. of the men and 48 per cent. of the women from 21 to 50. From the diet records it was established that the men living in their own homes consumed from 15 to 34 per cent. more energy and protein and up to 50 per cent. more Fe per kg. bodyweight than the women in the same age groups. In both sexes protein supplied 14 per cent. of the total energy. There was a positive correlation between dietary protein and Fe and Hb values.

The men in the county home had Hb values similar to those living in their own homes, but the packed cell volume was lower. Although the women had comparable intakes of protein and Fe in proportion to total energy and were all except one past the menopause they had low Hb values in comparison with men of the same age and circumstances. At every level of protein and Fe intake the percentage of men with an Hb value of 14 g. per cent. or more was about twice that of the women, at least up to 75 years of age.

2. Of the same 577 normal men and women the venous blood sugar values of 430 who had eaten a carbohydrate meal 2 hr. or more previously were recorded. Forty-five men were living in the county home and the other subjects in their own homes.

The average venous blood sugar value was 101 mg. per 100 ml. The values, when calculated for 5-year age intervals and separated by sex, showed little variation, but there was a slight indication of an increase with age in the women. Hyperglycaemia occurred in 2.1 to 5.6 per cent. of men and 1.3 to 4.4 per cent. of women. Glycosuria occurred to different extents in 36 subjects, in 18 of whom urine sugar was over 130 mg. per 100 ml. Glycosuria and hyperglycaemia occurred in 8 men and 2 women; 4 women and 14 men had glycosuria but normal or low blood sugar values.

The men in the county home over 65 years of age had an average blood sugar value of 85 mg. per 100 ml., which was significantly lower than that of men of the same age living at home. Six subjects had hyperglycaemia and 3 had diabetes.

In the women there was a moderate positive correlation between fat intake and blood sugar; there was no correlation between blood sugar and carbohydrate or protein intake in either men or women.—G. F. Garton.

EXPERIMENTAL STUDIES OF IMMUNITY AND MICRO-ORGANISMS

- 3987
DUBOS, R. J. Effect of metabolic factors on the susceptibility of albino mice to experimental tuberculosis. *J. Exp. Med.*, 1955, **101**, 59-84. [Labs., Rockefeller Inst. Med. Res.]
- Mice after weaning received Purina chow to appetite or an experimental diet and were infected intravenously with virulent or attenuated strains of human or bovine tubercle bacilli. Groups of 10 to 20 mice were used and each experiment was repeated at least 3 and up to 10 times.
- Mice fed to appetite on chow, or on diet 191 (Abst. 1647, Vol. 15), or on the Sherman diet of wheat flour 66 parts, skimmed milk 33 parts and salt 1 part, survived much longer than those fed on the same diets but deprived of food for 30 consecutive hours each week. Mice receiving 75 per cent. of the voluntary food intake of others on the Sherman diet gained little weight, but survived as long as those fed to appetite.
- Mice on diets containing 4 or 5 per cent. skimmed milk of 37 per cent. protein content, plus 20 per cent. groundnut oil, were not more susceptible to tuberculosis than those receiving chow, Sherman diet or diets with 15 to 34 per cent. skimmed milk, but when the groundnut oil was replaced by cerelose or cocoa butter the mice on low-protein diet had very poor resistance. With 15 or 20 per cent. skimmed milk there was no obvious effect of cerelose, groundnut oil, cocoa butter or lard at the 20 per cent. level.
- The addition of 3 to 10 per cent. sodium citrate to any of the diets shortened the survival of infected mice; so did 1 per cent. glutarate in the drinking water, but 5 per cent. alcohol did not.
- There was no correlation between the effects of a diet on growth and on resistance to infection. Dinitrophenol, 0.025 per cent., or thyroid extract, 0.003 per cent., while reducing growth did not affect resistance, but larger doses enhanced susceptibility after a latent period of 18 days to 4 weeks. Citrate and dinitrophenol each brought about slowly progressive fatal disease in most of the mice infected with attenuated BCG-P.
- The results are considered compatible with the hypothesis that decreased resistance to infection may be caused by metabolic changes leading to depletion of glycogen reserves, reduced glycolytic activity of inflammatory cells, or increased concentration of some polycarboxylic acids and ketones in the tissues.—D. Duncan.

BRYANT, M. P. and DOETSCH, R. N. Factors necessary for the growth of *Bacteroides succinogenes* in the volatile acid fraction of rumen fluid. *Science*, 1954, **120**, 944-945. [Dairy Husb. Res. Branch, U.S. Dept. Agric., Beltsville, Md.]
- Fractionation of rumen fluid by either extraction and chromatography showed the presence, mainly in the valeric acid fraction, of a growth substance essential for the cellulolytic rumen anaerobe *Bacteroides succinogenes*. The organism was cultured in a complex medium, the carbohydrate being either glucose, with which growth was estimated turbidimetrically, or cellulose, when growth was estimated by visible loss of the latter.
- Commercial volatile fatty acids from C_2 to C_8 and isomers of C_2 to C_6 acids gave no significant benefit when added singly to the basal medium; but if any one of the branched-chain acids isobutyric, isovaleric, or DL-methyl-n-butyric, plus any one of the straight-chain acids C_5 to C_8 , was added, good growth occurred. The straight-chain components in rumen fluid were thought to be n-valeric and n-caproic acids. The minimum concentrations of isovaleric and n-valeric acids for good growth were about 1.5 and 3 μM , respectively, per 10 ml. medium.—E. S. McKay.

MANN, S. O. and OXFORD, A. E. Relationships between viable saccharolytic bacteria in rumen and abomasum of the young calf and kid. *J. Gen. Microbiol.*, 1955, **12**, 140-146. [Rowett Res. Inst., Bucksburn, Aberdeenshire.]
- From rumen contents of 8 young calves streptococci were isolated which, though belonging to

Lancefield group D, differed in some respects from streptococci which have been described in older animals. Abomasal contents of very young calves and kids supported a population of lactobacilli, identified as *Lactobacillus fermenti*, *L. acidophilus* and *L. acidophilus* var. *caprae*.—J. C. Appleby.

3993

STALLCUP, O. T. The release of ammonia nitrogen from urea, ammoniated molasses, and soybean oil meal in the presence of rumen micro-organisms. *J. Dairy Sci.*, 1954, **37**, 1449-1460. [Dept. Animal Indust., Arkansas Agric. Exp. Stat., Fayetteville.]

The artificial rumen was used to estimate the amount of free ammonia N liberated from urea, ammoniated cane molasses and ammoniated invert molasses containing equivalent amounts of N, before and at intervals during incubation for 6 hr. at 40° C. with rumen microflora and a mineral solution resembling concentrated saliva. A control was run with the medium alone. In a second series soya bean meal was compared by the same technique with the 2 samples of molasses. In the third series the materials were incubated with urease for 1 hr. In the fourth series a 3-year-old steer with a rumen fistula was fed first on a ration of lespedeza hay alone, after which the ammoniated substances were introduced into the rumen and the contents were sampled for free ammonia at intervals.

Some free ammonia was present in the ammoniated molasses, but the amount did not increase significantly during incubation with microflora or in the presence of urease. Considerable amounts of free ammonia were liberated from urea both *in vitro* and *in vivo* in the presence of microflora and also in the presence of urease. Release of ammonia N from soya bean meal was small, but increased in the presence of urease. The total amount released was small compared with that released from urea.—J. S. Thomson.

3994

ROBINSON, R. Q., DOETSCH, R. N., SIROTNAK, F. M. and SHAW, J. C. Production of lactic acid and an iodine staining substance by bovine rumen bacteria. *J. Dairy Sci.*, 1955, **38**, 13-19. [Dept. Bacteriol., Univ. Maryland, College Park.]

Washed cell suspensions of rumen bacteria were prepared and used as described earlier (*J. Dairy Sci.*, 1953, **36**, 825). Conditions governing production of lactic acid and synthesis of iodine-staining polysaccharide were investigated. Experiments were made at pH 5.6, 6.9 and 8.0, and with varying concentrations of different substrates, over 72-hr. periods.

Formation of polysaccharide from hexose sugars

Vol. 25, No. 3

was more readily detected at pH 6.9 than at 5.6 or 8.0, and particularly with relatively high concentrations of substrate. Polysaccharide appeared to be utilised as reserve food material. Utilisation was increased by the addition of a mineral salt solution, but not by adenylic acid or by Mg ions; synthesis was inhibited by NaF and by the sodium salt of ethylenediaminetetra-acetic acid.

Lactic acid was not formed from xylose or arabinose, nor appreciably from pyruvate, malate or succinate, and with moderate amounts of suitable substrate it accumulated without dissimilation only at pH 5.6 and 8.0. With large amounts of substrate, 2000 μ M, lactic acid did accumulate at pH 6.9, which agrees with the results of feeding cattle on excessive amounts of carbohydrate. Lactic acid levels at pH 6.9 were affected by the speed of centrifuging used in preparation of the bacterial cell suspension.—J. C. Appleby.

3995

JURTSCHUK, P. (Jr.), DOETSCH, R. N., McNEILL, J. J. and SHAW, J. C. In vitro studies of the effect of aureomycin and terramycin on mixed suspensions of bovine rumen bacteria. *J. Dairy Sci.*, 1954, **37**, 1466-1472. [Dept. Bacteriol., Univ. Maryland, College Park.]

Aureomycin and terramycin suffered some non-specific inactivation when incubated with heated or unheated mixed suspensions of rumen bacteria. In the presence of antibiotics the bacteria did not readily utilise xylose, arabinose, glucose, maltose or cellobiose. Penicillin and terramycin actively inhibited the growth of most of 16 pure cultures of bacteria when the antibiotics were in concentrations of 1 and 2 μ g. per ml., respectively. Aureomycin, streptomycin and chloromycetin inhibited only a few cultures. Aureomycin and terramycin at 25 μ g. per ml. completely prevented growth of bacteria on Hungate's medium.

D. Duncan.

3996

FRANÇOIS, C. and MICHEL, M. Action de la pénicilline et de l'aureomycine sur les propriétés désammanantes de la flore intestinale du porc. [Effect of penicillin and aureomycin on the deaminating properties of the intestinal flora of the pig.] *C.R. Acad. Sci.*, 1955, **240**, 124-126.

A sample of flora obtained by fractional centrifuging of pig intestinal contents was cultured *in vitro*. Liberation of ammonia was inhibited by addition of aureomycin or penicillin. A culture obtained from pigs fed on these antibiotics inhibited deamination in glutamic and aspartic acids, arginine, citrulline, ornithine, histidine, β -alanine and lysine. The addition of aureomycin to a culture obtained from control pigs also

inhibited deamination of these acids (with *D*-alanine substituted for β -alanine) but penicillin was less active and did not inhibit deamination of aspartic acid, ornithine and *D*-alanine.—A. Hepburn.

3997

MICHEL, M. and FRANCOIS, A. C. Relation entre l'influence des antibiotiques sur la croissance du porc et l'inhibition des déaminases de la flore intestinale. [Relation between the effect

of antibiotics on growth of pigs and the inhibition of deaminases of the intestinal flora.] *C.R. Acad. Sci.*, 1955, 240, 808-810.

A direct relation was established between the stimulation of growth produced in the pig by different antibiotics and their inhibitory action on the deamination of arginine and citrulline by the intestinal flora *in vitro*.—A. Hepburn.

MISCELLANEOUS FEEDING EXPERIMENTS

3998

ADOLPH, W. H., SHAMMAS, E. I. and HALABY, S. H. The nutritive value of legume proteins and legume-wheat mixed proteins in Near East diets. *Food Res.*, 1955, 20, 31-34. [Nutrit. Lab., American Univ. Beirut, Lebanon.]

Weanling rats, usually 10 for each mixture, were used in paired feeding experiments lasting 4 weeks during each of which 7, 8, 9 and 10 g. daily of the mixture, with 10 per cent. protein, were given. The legumes were usually cooked. Protein efficiency measured by g. weight increase per g. protein consumed was: chick pea uncooked 1.47, cooked 2.05, lentil 1.15, broad bean 1.17, kidney bean 1.51, parboiled wheat 1.44, wheat uncooked 1.39, 1:1 mixture chick pea and parboiled wheat 2.10, 1:1 lentil:parboiled wheat 1.55, 1:1 broad bean:parboiled wheat 1.62, 1:1 broad bean:chick pea 1.49, 1:1:1 broad bean:chick pea:parboiled wheat 1.94, 2:1 parboiled wheat:yoghurt 1.93.

The last 2 of these, known, respectively, as *falafil* and *kishk*, are commonly in use in the Near East and show that rural peoples with limited resources may have arrived at combinations of high nutritive value.—D. Harvey.

3999

CLARK, H. E., HOOPER, A. S. and McCORD, M. L. The nutritive value of the proteins of beef extracted with different solvents, and of egg, milk and wheat germ for the growing rat. *J. Nutrition*, 1955, 55, 63-79. [Dept. Foods Nutrit., Kansas State Coll., Manhattan.]

The simultaneous dehydration and defatting of beef by refluxing with ethylene dichloride or propylene reduced its nutritive value for growing rats. Several other proteins were unaffected. Growth was improved by methionine or cystine. Ether, heptane and trichloroethylene were satisfactory solvents from this point of view. The regression of daily weight gain on N intake was significantly greater for egg than for beef, milk and wheat germ, which were the same. Regressions of N balance on intake per 100 sq. cm. surface

area were similar for egg and milk and significantly higher than for beef or wheat germ. In N retention egg, but not beef, effectively supplemented milk, and both improved wheat germ.

A. Hepburn.

DESEHPANDE, P. D. and RADHAKRISHNA RAO, M. V. The biological and supplementary nutritive value of (i) amaranth (*Amaranthus gangeticus*) and (ii) aconite bean (*Phaseolus aconitifolius*). 2. *Indian J. Med. Res.*, 1954, 42, 515-520. [Dept. Nutrit., Haffkine Inst., Bombay 12.]

For part 1 see Absts. 4276, Vol. 24.

The biological value and digestibility of amaranth leaves at the 10 per cent. protein level, estimated by N balance trials with rats, were 67 and 85 per cent.; aconite bean at the 5 and 10 per cent. level had biological values of 56 and 60 per cent. and digestibility coefficients of 83 and 87 per cent. Added at the 5 per cent. level to a poor diet containing 78.5 per cent. rice, amaranth had a supplementary nutritive value for rats. Aconite bean improved the diet only by increasing the total protein content.—A. Hepburn.

PATWARDHAN, M. V. and VIJAYARAGHAVAN, P. K. Nutritive value of duck egg white. 1. Note on the essential amino-acid composition of duck egg white.

DIKSHIT, P. K. and PATWARDHAN, V. N. 2. A comparison of the digestibility and growth-promoting capacity of hen and duck egg whites.

NARASINGA RAO, B. S. and PATWARDHAN, V. N. 3. The presence of a growth inhibitor in duck egg white. 4. Antitryptic and growth inhibiting properties of the duck egg white ovomucoid. *Indian J. Med. Res.*, 1954, 42, 521-523; 525-532; 533-542; 543-554. [Nutrit. Res. Labs., Indian Council Med. Res., Coonoor, S. India.]

1. The low growth-promoting efficiency of duck egg white for rats, observed by Dikshit and

N.A. and R., July 1955

Patwardhan (*Current Sci.*, 1950, **19**, 18) could not be attributed to deficiency of any essential amino-acid.

2. Young rats fed on a steamed diet containing up to 9.4 per cent. duck egg white grew less well than those given hen egg white. With 15.5 per cent. duck egg white growth was better, but still less than with 8.2 per cent. hen egg white. The mean apparent digestibilities were 75.3 per cent. for duck and 84.2 for hen egg white. The difference was not so great as that previously found and did not account for the poor growth.

Rats fed on a rachitogenic diet containing 11.8 per cent. duck egg white neither grew nor developed rickets, but with 21.3 per cent. weight increased slightly and signs of rickets appeared.

3. The nutritive value of duck egg white as shown by growth of rats was improved by autoclaving, but that of hen egg white was not affected. Duck egg white dried in hot air was not improved further by autoclaving. Coagulated hen and duck egg whites produced similar growth. The precipitate from the incoagulable portion of duck egg white after half saturation with $(\text{NH}_4)_2\text{SO}_4$ contained the growth inhibitor.

4. The crude ovomucoids from hen and duck egg white had almost identical antitryptic activity.

Hen ovomucoid slightly improved growth in rats fed on casein, but duck ovomucoid retarded growth significantly, 2 per cent. of inhibitor giving a maximum inhibition of 30 per cent. Retardation of growth by duck ovomucoid was especially severe in a diet with Bengal gram as the source of protein. The growth of rats fed on acid or enzymic hydrolysates of casein was also depressed. This indicated that the growth-inhibiting activity of duck ovomucoid was possibly independent of its antitryptic activity.—A. Hepburn.

NARAYANA RAO, M. Supplementary value of buffalo butter fat to poor South Indian diet. *Indian J. Physiol. Allied Sci.*, 1954, **8**, 131-136. [Food Technol. Lab., Indian Inst. Sci., Bangalore 3.]

Groups of 6 young albino rats were studied. One group received a typical poor South Indian diet of raw milled rice 78.5, tur dahl 5, salt 0.3, non-leafy vegetables 8.2, leafy vegetables 2.1, whole milk powder 0.9 and oil 5 per cent.; the other 3 groups received the same diet supplemented with 5 per cent. buffalo butterfat, 5 per cent. buffalo butterfat plus 3 per cent. casein, or 5 per cent. buffalo butterfat plus 3 per cent. Ca-free casein. Food was given to appetite; weights were recorded from the second week of experiment and faeces and urine were collected during the last week and analysed for N and Ca.

The addition of butterfat alone to the rice diet adversely affected growth and produced more serious pathological conditions than the rice diet alone. When casein was added to the butter the effects did not appear and there was an acceleration of growth which was so great that it could not be attributed to the effect of casein alone. The rats given Ca-free casein grew as well as those given casein containing Ca. It is believed, therefore, that the rice diet is deficient in a substance or substances essential for the normal utilisation of fat and that this substance is supplied by casein. It is suggested that the substance may be an essential amino-acid. There was no statistical difference between the Ca and N balances of the rats given different diets.—G. F. Garton.

4004

NARAYANA RAO, M. and SWAMINATHAN, M. The digestibility of safflowerseed and nigerseed oils. *Indian J. Physiol. Allied Sci.*, 1954, **8**, 61-68. [Central Food Technol. Res. Inst., Mysore.]

Safflower seed oil, niger seed oil and groundnut oil were less rapidly hydrolysed by lipase from pig pancreas or castor seed than was ghee. Digestibility coefficients of the 4 fats, estimated by trials with rats, were not significantly different.

A. Hepburn.

4005

KREHL, W. A., COWGILL, G. R. and WHELDON, A. D. Non-deleterious effects of polyoxyethylene esters in the nutrition of rats and cats. *J. Nutrition*, 1955, **55**, 35-61. [Dept. Biochem., Yale Nutrit. Lab., Sch. Med., Yale Univ., New Haven, Conn.]

Polyoxyethylene mono- and di-stearates, oleates and laurates and the octamer of ethylene oxide were included at 6 per cent. in the diet of rats. Polyoxyethylene-8-monostearate, the ester derived

from the octamer, was given at 10 and 20 per cent. to rats and cats. After the end of the experiments, which lasted over 1 and 1½ years for the cats and rats, respectively, no significant pathological difference was found between experimental and control animals. The inclusion of polyoxyethylene stearates up to the 20 per cent. level was considered quite safe, but their low palatability and the lack of nutritive value of the polyoxyethylene moiety make it practicable only at low levels.

GRAHAM, W. D., TEED, H. and GRICE, H. C.

Chronic toxicity of bread additives to rats.

GRAHAM, W. D. and GRICE, H. C. **Chronic toxicity of bread additives to rats.** *J. Pharm.*, 1954, **6**, 534-545; 1955, **7**, 126-134. [Food and Drug Labs., Dept. Nat. Health and Welfare, Ottawa.]

Bread containing 50 times the normal concentration of chlorine dioxide, propyl gallate and butylated hydroxyanisole, polyoxyethylene monostearate or sodium propionate was given to rats as 75 per cent. of their diet. Adequate amounts of all known essential substances were also given. During 12 months no harmful effect on growth or mortality of the rats was found, and no detectable effect on organ weights or on histopathology of the tissues. There was no evidence of any synergistic effect of the addition of high concentrations of more than one possible toxic substance to the bread.

The work reported in the previous paper was repeated but the toxic substances were added to the bread ingredients and given thus to the rats, instead of being mixed with them, having water added and being baked into bread. The only difference in effect on the rats was that the sodium propionate depressed growth during the first few weeks of feeding; it did not influence mortality. In addition to the points examined in the rats given the bread, these rats were examined for Hb content of the blood, and no detectable effect of the possible toxic substances was found.

DICKSON, W. M., PATTERSON, E. B., STERN, J. R. and MCGINNIS, J. **The effect of terramycin or fish solubles, or both, on the growth, adrenal glands and gonads of the rat.** *J. Nutrition*, 1954, **54**, 631-641. [Dept. Vet. Physiol., State Coll. Washington, Pullman.]

Gains in weight of the body, adrenals and sex organs and in tail length were studied in castrated and uncastrated male and female rats after 21, 49 and 77 days' feeding after weaning on diets supplemented with fish solubles or terramycin or both.

Fish solubles promoted early post-weaning

growth. Terramycin acted as a growth stimulant only in animals subjected to surgical stress. Neither supplement affected the weight of the male sex organs. Both may increase the weight of the adrenal. Fish solubles added to a semi-purified diet caused a significant increase in weight of ovaries and uterus.—J. V. Evans.

COATES, M. E., DAVIES, M. K. and KON, S. K. **The effect of antibiotics on the intestine of the chick.** *Brit. J. Nutrition*, 1955, **9**, 110-119. [Nat. Inst. Res. Dairying, Univ. Reading.]

In chicks fed on a normal mash for 2, 3 or 4 weeks, penicillin at the rate of 45 mg. per kg. diet significantly reduced the weight of the small intestine relative to bodyweight, and to some extent also its length. The changes were not accounted for by fat or water content. In "uninfected" chicks, in which penicillin did not increase growth, the intestine was also unaffected. Arsanilic acid was similar in effect to penicillin, chloramphenicol less consistently so. Raw liver also had some effect on both bodyweight and intestine, but it was not significant.—D. Duncan.

DASLER, W. (with MOSBY, M.) **Incisor ash versus femur ash in sweet pea lathyrism (odoratism).** *J. Nutrition*, 1954, **54**, 397-402. [Dept. Biochem., Chicago Med. Sch., Ill.]

Groups of 6 or 12 male and female weanling rats were given experimental and control diets containing 50 per cent. sweetpea seeds and 50 per cent. edible peas, respectively. A second control diet consisted of finely milled Rockland rat diet. After 3 weeks the animals were killed and both lower incisors and one femur were removed from each for estimation of ash.

The mean femur ash was significantly lower in rats of both sexes given the sweetpea diet than in those given control diets. The mean incisor ash was significantly higher in rats with advanced sweetpea poisoning than in controls.—G. F. Garton.

TRIBE, D. E. **Choice of diet by rats. 4. The choice of purified food constituents during growth, pregnancy and lactation.** *Brit. J. Nutrition*,

N.A. and B., July 1955

1955, 9, 103-109. [Sch. Vet. Sci., Univ. Bristol.]

See also Absts. 373, 696, Vol 24.

Fifteen female rats weighing about 100 g. were placed in individual cages and allowed to select their food from containers of maize starch, glucose, margarine, yeast, casein, McCollum's salt mixture No. 185 and cod liver oil. The containers were identical in shape and colour and their positions were altered every second day. Tap water was given to appetite. After 6 weeks all the rats were mated and their food selection throughout pregnancy and 3 weeks of lactation was recorded. Five male and 5 female young were selected at weaning and their food preferences were recorded during 4 weeks of active growth.

Two of the 15 rats failed to thrive, but the other 13 chose a diet similar to those recommended as stock diets; no food was completely ignored. During pregnancy and lactation the diets selected were deficient in energy and protein and the does were unable to rear normal litters. The young rats were totally unable to select suitable diets and 8 of the 10 died during the 4 weeks.

ANAND, B. K., DUA, S. and SHOENBERG, K. **Hypothalamic control of food intake in cats and monkeys.** *J. Physiol.*, 1955, 127, 143-152. [Dept. Physiol., Lady Hardinge Med. Coll., New Delhi.]

Bilateral lesions were made in the hypothalamus of 16 cats and 17 monkeys (*Macacus*), which were then fed to appetite on their usual diet.

Four cats and 4 monkeys, although awake and active, would not eat even when food was placed in their mouths; they were fed by stomach tube and kept alive for 1 to 4 weeks, but they did not begin to eat. Two more monkeys could be made to eat when food was placed in their mouths. All these animals were found to have lesions in the lateral hypothalamus in the plane of the central part of the median eminence.

Two cats and one monkey developed an increased desire for food, and in these animals the medial hypothalamic area in the region of the median eminence was destroyed. The other 10 cats and 10 monkeys ate normally, and both hypothalamic regions described were intact. When both regions were destroyed, which was done later in one cat and one monkey, eating ceased.

Centres in the hypothalamus thus regulate the feeding reflexes both by facilitation and by inhibition.—D. Duncan.

4013

ANAND, B. K. and DUA, S. **Feeding responses induced by electrical stimulation of the hypo-**
Vol. 25, No. 3

thalamus in cat. *Indian J. Med. Res.*, 1955, 43, 113-122. [Dept. Physiol., Lady Hardinge Med. Coll., New Delhi.]

Multilead electrodes, one set on each side, were implanted in different parts of the hypothalamus of 25 cats. At least a week after operation the cats were subjected to electrical stimulation for 1 hr. on each of 4 to 7 consecutive days in one hypothalamic area at a time.

In 8 cats, stimulation produced an increase in meat and milk intake on the day of stimulation, with only a day or two's lag in returning to normal when stimulation stopped. In all these cats the electrodes were in the lateral hypothalamus in the same rostro-caudal plane as the ventromedial nucleus.

In 5 cats stimulation led to some decrease in food intake on the day of stimulation, but never to complete loss of appetite. The electrodes in these cats were in the medial hypothalamus in the region of the ventromedial nucleus.

In cats which showed no change in food intake after stimulation the electrodes were always well outside the regions described above.

There was no change in rectal temperature, circulating eosinophil count or gastric secretion which could be related to change in food intake, and changes in blood sugar were somewhat irregular, though blood sugar tended to rise when appetite increased and fall when it was reduced.

LARSSON, S. **On the hypothalamic organisation of the nervous mechanism regulating food intake.**
1. **Hyperphagia from stimulation of the hypothalamus and medulla in sheep and goats.**

FORSSBERG, A. and LARSSON, S. 2. **Studies of isotope distribution and chemical composition in the hypothalamic region of hungry and fed rats.** *Acta physiol. scand.*, 1954, 32, Suppl. 115, 1-40; 41-63. [Dept. Physiol., Kgl. Veterinärhögsk., Stockholm.]

1. In experiments with goats and sheep in which electrical stimulation was used, 8 points where stimulation caused increased appetite were mapped in the hypothalamus and 2 in the medulla. Associated licking, chewing and rumination movements were seen. In similar experiments in which solutions of 3 or 5 per cent. NaCl or 25 per cent. sucrose were injected into the hypothalamus of goats similar effects were produced. No effect was found on the blood sugar and no difference in effect between the solutions.

2. Rats were given $\text{NaH}^{32}\text{PO}_4$, ^{14}C -glucose or $\text{NaH}^{14}\text{CO}_3$ intraperitoneally and measurements were made in samples from 3 areas of the hypothalamus, one of which (C) included the centre regulating food intake, and 2 neighbouring

areas (A and B). Total activity and that of a number of fractions were estimated, and the total activities of blood, liver, muscle and cerebrum.

In hungry and fed rats total activity was similar for ^{32}P , but more appeared in the C than in the A and B areas in the hungry than in the fed animals. The concentration of P as adenosinetriphosphate and creatine phosphate was higher in C than in B samples from hungry rats, but in fed rats the opposite was true. In the other tissues ^{32}P activities differed, but there was no significant difference between hungry and fed groups. The findings for ^{14}C in both forms agreed with those for ^{32}P .

The possibility is discussed that the concentration of adenosinetriphosphate is of fundamental importance in these biochemical reactions.

MEYER-LOHMANN, J. Über den Einfluss täglicher Futtergaben auf die 24-Stunden-Periodik der lokomotorischen Aktivität weisser Mäuse. [Effect of the daily food intake on the 24-hour locomotor activity of white mice.] *Pflügers Arch.*, 1955, 260, 292-305. [Physiol. Inst., Univ. Göttingen.]

The mice in actograph cages received a diet of, per cent., oats 60, wheat 30, shrimps 5 and sunflower seed 5. Three cages were in constant darkness during each test and 3 were illuminated at about 150 lux for from 7 to 19 hr. daily. There was an 8-day fore-period for each study.

In mice deprived of diurnal environmental change such as light and temperature rhythms the daily cycle of activity tended to take on a 23-hr. rhythm. When mice were fed once daily but allowed enough food to last all day, 8 g., there was only a slight peak of activity with 24-hr. periodicity superimposed on the 23-hr. cycle. When mice were fed once daily, but the intake and time spent in eating were restricted, the daily activity became completely dependent on the feeding cycle.

With a natural or artificial cycle of light and darkness the activity was primarily conditioned by light changes but, as in darkness, a food stimulus increased by reduced intake could cause a shift in the peaks of activity.—D. Duncan.

4016

RICHTER, C. P. and RICE, K. K. Comparison of the effects produced by fasting on gross bodily activity of wild and domesticated Norway rats. *Amer. J. Physiol.*, 1954, 179, 305-308. [Psychobiol. Lab., Med. Sch., Johns Hopkins Univ., Baltimore, Md.]

In control periods the average daily activities of wild and domesticated Norway rats were

similar. When they were deprived of food their activities, expressed as percentages of those of control periods, were for the wild 242 and for the domesticated 132. During the control period intake of food by the domesticated rats was about 10 per cent. less than by the wild and, in control and fasting periods, the water intake of the domesticated was the smaller.

The lower response in activity during starvation on the part of the domesticated rat would, it is concluded, tend to decrease its chance of survival.

KAMRIN, B. B. Local and systemic cariogenic effects of refined dextrose solution fed to one animal in parabiosis. *J. Dent. Res.*, 1954, 33, 824-829. [Dept. Anat., State Univ. New York Med. Coll., Brooklyn.]

The left members of 18 parabiotic pairs of rats, which received a balanced diet for 16 to 35 days, and the right parabionts, which received in addition 1 ml. 25 per cent. glucose daily, had mean caries rates of 0.17 and 2.43. Corresponding values for 10 pairs of parabiotic rats after 36 to 105 days

N.A. and R., July 1955

were 0.69 and 5.00. The differences were statistically significant. The greatest incidence of fissure caries occurred most rapidly when glucose was given immediately after weaning. The 13 parabolic pairs used as controls were free from caries

except for one pair aged 171 days, in which one molar cavity developed in each rat. Growth was normal in all and there was no significant difference in blood sugar between right and left parabionts.

MALUCELLI, P. Prove di alimentazione del baco da seta. Consumo di foglia di gelso in rapporto alle esigenze alimentari di comuni razze e microci del *Bombyx mori*. [The feeding of silkworms. Consumption of mulberry leaves in relation to the requirements of common strains and crosses of *Bombyx mori*.] *Ann. Sper. agrar.*, 1954, 8, 865-866. [Staz. Sper. Gelsicolt. Bachicolt., Ascoli Piceno.] English summary.

The consumption of mulberry leaves was studied with batches of 500 silkworm larvae during the third, fourth and fifth stages of development. Six strains and 2 crosses were compared, including old and new improved types.

The large white strains, White Italian and White Adrianople, ate the largest quantities per larva, but on the commercial basis they and the White Chinese ate the smallest quantities per ounce. The new types were much more efficient than the old in conversion of feed in terms of weights of cocoon and silk produced.

It is concluded that the white strains and crosses developed in Italy can compete successfully with those developed in Japan.—D. Duncan.

LIPKE, H. and FRAENKEL, G. The toxicity of corn germ to the meal worm, *Tenebrio molitor*. *J. Nutrition*, 1955, 55, 165-178. [Dept. Entomol., Univ. Illinois, Urbana.]

In the germ of maize there is a toxic substance

Vol. 25, No. 3

which inhibits growth of the larvae of the meal worm, *Tenebrio molitor*. If the germ or the whole maize is autoclaved before feeding, good growth results. The possibility that the inhibition of growth was due to a deficiency was ruled out by failure to get improved growth when known food essentials were added to the basal diet containing the unheated maize germ. When lysine and tryptophan were added to the maize from which the germ had been removed good growth resulted.

The toxic substance was not extracted by ethyl ether. It was extracted from the germ with 0.25 N H₂SO₄. From this extract a fraction was concentrated by dialysis and lyophilisation which was toxic at 1.6 per cent. of the diet.—G. C. Hunter.

4023

EDWARDS, R. L. The effect of diet on egg maturation and resorption in *Mormoniella vitripennis* (Hymenoptera, Pteromalidae). *Quart. J. Microscop. Sci.*, 1954, 95, 459-468. [Dept. Zool., Univ. Hull.]

The hymenopteran *Mormoniella vitripennis* is parasitic on the pupae of muscoid flies. Parasites were obtained in their late pupal stage by opening host puparia, and the imagines were paired with males when they emerged, but were then fed on honey, or starved, or fed on honey for 48 hr. and then allowed access to a supply of puparia of the housefly so that they laid eggs and fed on host blood.

In ovaries of females fed on honey there was a fairly large number of freshly matured eggs always available, maturation and resorption just keeping pace for about 16 days, after which time the number maturing began to fall. In starved females few eggs matured and resorption began early; death occurred in about 5 days. In females killed after access to hosts the number of mature eggs was small because they had been deposited; the number of immature eggs was greatly increased. The peak of the maturation rate and the number of eggs deposited was on the third day after the first meal of host blood. Females allowed hosts for 48 hr. and then starved died more quickly than those never fed, probably because their fat-bodies were depleted.

5. HUMAN DIET IN RELATION TO HEALTH AND DISEASE

DIET

REQUIREMENTS

4024

- Cox, C. P. and CLARKE, P. M. Fallacies in nutritional requirement experimentation. *Arch. Biochem. Biophys.*, 1955, **54**, 246. [Nat. Inst. Res. Dairying, Univ. Reading.]

The measurement of changes in a biological response as the amount of a nutritional factor is varied in the diet was discussed by Almquist (Abst. 1058, Vol. 25). It was concluded that, since the law of diminishing returns so often applies in these cases, there would be less chance of detecting significant differences in response at higher than at lower values of a factor, if the levels being tested were equally spaced. He suggested that this might lead to underestimation of nutritional requirements and, as a solution, proposed the choice of levels of the factor with equal logarithmic spacing between them. This procedure is thought by the authors not to be desirable and they suggest that instead there should be increased replication at the higher levels of the factor. They note also that optimum nutritional requirements of animals are not necessarily arrived at by finding maximum individual biological responses to individual nutritional factors.—I. McDonald.

- DOBOS, F., HAMAR, N. and TARJÁN, S. Adäquater und minimaler Kochsalzbedarf in der Hitzearbeit, unter besonderer Berücksichtigung der Hitzearbeiter in der ungarischen Eisen- und Stahlindustrie. [Adequate and minimum salt requirement during work in a hot environment, with special reference to workers in the Hungarian iron and steel industry.] *Acta med. hung.*, 1954, **6**, 433-451. [Staatl. Inst. Arbeitshyg., Budapest.] Russian summary.

Investigations were made on 82 workers of the iron and steel industry, acclimatised to heat, to study their salt, water and osmotic balances under the usual working conditions.

The workers consumed during work 5 to 6 g. NaCl, and outside their work 7 to 8 g. The salt intake did not depend on the requirement corresponding to the amount of sweat, but was a function

of food taken to cover their energy requirement. The daily intake of 12 or 13 g. NaCl is adequate to replace the salt loss only if the amount of sweat does not appreciably exceed 5 litres. With this intake some workers, when they lost for some days 10 litres of sweat, showed signs of salt deficiency. When the amount of sweat exceeds 5 litres, the minimum salt requirement in g. is reckoned to be approximately the amount of sweat in kg., and the adequate intake of salt in g. is about twice the amount of sweat in kg. The usual salt consumption of the Hungarian iron and steel workers thus assures an adequate intake for sweating up to 5 litres, and a minimum intake for about 10 litres. If the salt intake reaches the minimum level, but is below the adequate level day after day, some workers may drink as much water as to cause dilution of the extracellular fluid, with danger of water intoxication. Hence, if the amount of sweat exceeds 5 litres day after day, the worker should drink during working hours aerated water containing 0.1 per cent. NaCl. The usual salt intake outside work will then be adequate to replace salt loss from 7 to 8 litres of sweat; if the amount of sweat is still greater, the salt intake outside work also should be increased.

M. B. Richards.

- DOBOS, F., HAMAR, N., TARJÁN, S. Klassifizierung der Hitzearbeit in der ungarischen Eisen und Stahlindustrie vom Gesichtspunkt des Gesundheitsschutzes, unter besonderer Berücksichtigung des Kochsalzbedarfes der Hitzearbeiter. [Classification of hot work in the Hungarian iron and steel industry from the point of view of protecting health with special reference to salt requirement of workers in heat.] *Acta med. hung.*, 1954, **6**, 463-474. [Staatl. Inst. Arbeitshyg., Budapest.] Russian summary.

From 290 investigations of the most important types of hot work in the Hungarian iron and steel industries workers could be placed in 3 categories. 1. Those exposed to such conditions that the amount of sweat lost during their working hours at all times of the year, except on very cold winter days, exceeds 5 litres daily. For them it is essential that during work throughout the whole year they should drink aerated water with 0.1 per cent. NaCl. 2. Those who from mid-May to mid-September lose more than 5 litres sweat daily during the hours of work; for this period their drinking water during work should contain 0.1 per cent. NaCl. 3. Those working in less severe

N.A. and B., July 1955

conditions and whose loss of sweat does not exceed 5 litres, except perhaps on occasion. Special measures are not required for them.

The types of work in each category are given.
M. B. Richards.

NYHAN, W. L. and WESSEL, M. A. *Neonatal growth in weight of normal infants on four different feeding regimens. Pediatrics*, 1954, 14, 442-448. [Dept. Paediat., Sch. Med., Yale Univ., New Haven, Conn.] Spanish summary.

Babies were in 4 groups, each of 100, either breast-fed on a flexible schedule or bottle-fed on a 4-lr. schedule in nursery conditions or in those being studied at Yale whereby they remain with their mothers continuously instead of merely being brought at intervals for feeding. They were weighed daily before the first morning feed during the first week of life. For the milk mixture given to the bottle-fed infants see Nyhan, *Pediatrics*, 1952, 10, 414; after leaving hospital they had a 1:1.5 mixture of evaporated milk and water with 5 per cent. maize syrup. The groups were comparable as regards birthweight and sex, but not colour or parity of mother.

Breast-fed babies lost significantly more weight in the first few days than bottle-fed babies, the effect being more marked with babies fed in the nursery than with those under the other system; with both living arrangements the babies fed to schedule lost more than those fed on a flexible schedule. The differences are ascribed to differences in total food intake, and there was evidence to suggest that the greater losses of the breast-fed babies were due not to differences between human and cow's milk but to the fact that the bottle-fed babies were fed from the first day of life, the breast-fed babies from the onset of lactation.

By 6 weeks the breast-fed nursery group had gained significantly more than the bottle-fed nursery group; other differences were not significant.—W. M. Deans.

SINTOS, A. Vergleichende Untersuchungen über Ernährung mit evaporierter Milch und Sammelfrauenmilch bei jungen Säuglingen. Zugleich ein Beitrag zur kritischen Beurteilung

Vol. 25, No. 3

ernährungsstatistischer Fragen. [Comparative studies of feeding young infants with evaporated milk and pooled breast milk. The critical assessment of nutritional statistics.] *Ztschr. Kinderheilk.*, 1955, 75, 634-642. [Kinderkrankenhaus Borgfelde, Allg. Krankenhaus St. Georg, Hamburg.]

The difficulties of making feeding tests on infants in such a way that the results can be tested statistically are discussed with reference to the literature. In the present study the subjects were premature infants or full-term infants under 3 months, all under the same care; 50 were fed solely on evaporated homogenised milk, generally diluted to supply 65.3 Cal. per 100 ml., and 49 on heat-sterilised breast milk from a milk bank. Statistical comparisons were also made after exclusion of infants with congenital defects or disorders likely to affect weight gain, and for healthy premature infants only. Though mean daily weight gains were 2 to 3 g. less for homogenised milk and showed greater scatter, the difference was not significant either for the whole groups or for the subgroups. Those on breast milk had fewer infections and digestive disturbances, but again the difference was not statistically significant. It was concluded that evaporated homogenised milk without a second carbohydrate is suitable even for very young infants.

WALKER, A. R. P., FLETCHER, D. C., STRYDOM, E. S. P. and ANDERSSON, M. *Food preparations used in weaning urban Bantu infants. Brit. J. Nutrition*, 1955, 9, 38-41. [Human Biochem. Unit, S. African Inst. Med. Res., Johannesburg.]

Samples of foods given by Bantu mothers to their children under 2 years of age were collected either in their homes or while they waited as out-patients at Baragwanath Hospital, Johannesburg. The 77 samples were of 5 types: thin cereal paps, proprietary mixtures of cereals and dried milk, dried-milk preparations, miscellaneous mixtures and thick cereal paps. In these groups they numbered 13, 14, 12, 26 and 12 and they were analysed for total solids, ash, protein and, with

some exceptions, fat. Standards for comparison were for protein 2.3 g. per 100 ml. as recommended for artificial milk mixtures and for energy 70 Cal. per 100 ml. as given for breast milk, both by Clements (*Infant Nutrition*, Bristol, John Wright and Sons, 1949). The percentages of samples in the groups deficient in protein were 100, 79, 43, 70 and 33 and in energy 100, 86, 75, 92 and 25.

The implications of overdilution, which may occur even when manufacturer's directions are carefully followed, are discussed.—D. Harvey.

4033

VEDRASHKO, V. F. and KATMANOVA, O. N. Vliyaniye kachestvenno razlichnogo pitaniya na fizicheskoe i nervopsicheskoe razvitiye zdorovykh detei doshkol'nogo vozrasta. [Influence of qualitatively different feeding on the physical and neuropsychological development of healthy children of school age.] *Vop. Pitani.*, 1955, 14, No. 1, 8-12.

A series of investigations was made on a group of 30 healthy schoolchildren aged from 6 to 7 years. First, an extensive series of anthropometric and biochemical investigations was used to determine the adequacy of a standard diet containing 3.5 g. protein per kg. bodyweight, with 60 per cent. of animal origin. It was next established that of 2 diets similar in all other respects, that in which animal protein comprised 65 per cent. of the total led to a greater positive N balance than did that in which animal protein formed only 40 per cent. of the total. There was a positive correlation between percentage animal protein and serum complement titre, phagocytic activity of leucocytes and strength of reaction to injurious stimuli. In a further group of children on the diet with 60 per cent. animal protein the time characteristics for the establishment, extinction and re-establishment of conditioned reflexes were within normal limits. It was found also that increasing the amount of eggs in the diet, without alteration in the total amounts of fat, carbohydrate and protein, led to a shortening of the latent period for the establishment and re-establishment of conditioned reflexes, to an increase in strength of reaction, and generally to a toning up of nervous processes.—D. W. Taylor.

GUTELIUS, M. F. Dietary needs and weeds in Louisiana. *Southern Med. J.*, 1954, 47, 1196-1198. [Dept. Paediat., Louisiana State Univ. Sch. Med., New Orleans.]

Questioning of mothers in the Paediatric Clinic of the Charity Hospital showed that the diet of children was usually too high in carbohydrate and, though adequate in energy, was more or less

deficient in most essential nutrients. The cheapest and simplest way to improve the diet would be by adding greens; two-thirds of a cup of cooked collards would suffice. Substitution of 1 pint of skimmed milk for $\frac{1}{2}$ pint of whole milk would be equally good and cheap.—E. H. Hume.

4035

RATNER, B., UNTRACHT, S., CRAWFORD, L. V., MALONE, H. J. and RETSINA, M. Allergenicity of modified and processed foodstuffs. 5. Soybean; influence of heat on its allergenicity; use of soybean preparations as milk substitutes. *Amer. J. Dis. Child.*, 1955, 89, 187-193. [Dept. Paediat., New York Med. Coll.]

Children, passively sensitised in the skin of the arm with serum containing soya bean antibody, were given different soya bean preparations by mouth. If no reaction occurred raw soya flour was given.

A liquid mix of soya flour heated at 165° F. for 20 min., cooled to 60° F. and kept at 260° F. for 60 min. and a similar preparation subsequently spray-dried evoked no reaction in children who later reacted to raw soya flour. An unheated spray-dried preparation and a liquid preparation treated for a short time with or without subsequent spray drying produced reactions, as did 2 commercial infant feeding preparations of unknown method of manufacture. Soya bean oil, soya sauce and a soya bean and maize mixture produced no reaction.

It is concluded that a properly modified soya bean preparation is ideal as a substitute for milk in the feeding of milk-sensitive infants.

N.A. and R., July 1955

In a study of 35 obese pregnant women the high energy intakes obtained by the research dietary history method of Burke (Abst. 1107, Vol. 18) were more in accord with physiological considerations than the lower intakes suggested by the results of a one-day food record submitted by the women.

MULDER, T. **Uitkomsten Nationaal Budgetonderzoek 1951. [Results of the National Budget Survey 1951.]** *Voeding*, 1954, **15**, 547-551.

Six new reports on data from the National Budget Survey 1951 deal with expenditure on food by families, classified by type of employment, income, residence and size of family. The report on agricultural labourers is the only one giving the actual amounts consumed, but no figures from it are quoted. Expenditures on vegetables, fruit, meat including bacon, milk, cheese and eggs are listed; these amounts, except for eggs, increase as the size of the family increases. The percentage of the total expenditure on food which is spent on the listed foodstuffs decreases in inverse ratio to the size of the family, except that on milk. Percentage of total income spent on food ranges from 48 per cent. in the lowest to 15 per cent. in the highest group. Labourers with small families spend a much higher percentage on food than do

sedentary workers with only slightly higher incomes. In large families the percentages differ much less. Expenditure on the listed foodstuffs by agricultural labourers is small, because of the use of homegrown produce. (See also Abst. 1083, Vol. 25).—M. Eddison.

4044

COX, M. L., SPENCE, B. D. and SCOLAR, F. I. **The protein, calcium, phosphorus, and magnesium content of nursery school lunches including "seconds".** *Child Development*, 1953, **24**, 181-188. [Texas Agric. and Mech. Coll.]

This continuation of previous work (Abst. 2648, Vol. 19; *Child Development*, 1952, **23**, 83) takes account of the second helpings of food or milk (allowed as desired provided all the original food had been eaten) consumed by the best and poorest eaters in an older and a younger group of nursery school children.

Second helpings made a considerable difference to the average Ca and P intakes of both groups and to the average protein intake of the younger but not of the older group. The poorest eater of the younger group had about one-fifth of the amount of protein recommended by the National Research Council, the best eater one-third. All the children had about one-half of the Ca recommended, and at least half the Mg considered necessary on the basis of Daniels' study (Abst. 3289, Vol. 11) but only $\frac{1}{3}$ g. P. Increased use of protein-rich foods other than milk is recommended.—W. M. Deans.

4045

EPFRIEHT, E. S., SIDWELL, V. D. and SWANSON, P. P. **Nutritive value of the diets of Iowa school children.** *J. Nutrition*, 1954, **54**, 371-388. [Iowa Agric. Exp. Stat., Ames.]

Children of both sexes numbering in all 1188 and between 6 and 18 years of age were chosen from rural communities and from towns with less and cities with more than 50,000 inhabitants (see Abst. 3955, Vol. 25). Data were from 7-day records made in the homes by mothers or by the children themselves and varied so little that all were grouped together. Intakes of energy and of 10 nutrients were calculated.

For girls intakes of energy, protein, Fe, vitamin B₁ and nicotinic acid were similar in that they rose steadily until age 12, remained constant to about 15 years and thereafter declined. Ca intake rose in the same way but fell after 12 years. Many of the girls, especially of those between 13 and 16 years, were getting less than the U.S. National Research Council (N.R.C.) recommended allowance. For boys there was a fairly continuous increase between 7 and 16 years in intakes of energy,

protein, Fe, vitamin B₁, nicotinic acid and riboflavin. Ca intake, unlike that of girls, increased greatly at 17 and was less than N.R.C. allowances only between 10 and 16 and at 18 years. From 6 to 12 years intakes by girls of all nutrients, except vitamins A and C, were about 10 per cent. less than those of boys; beyond 12 years the difference increased.

The ratios between some constituents were found to vary little. For a child population with similar feeding habits, whose mean daily protein intake is known, it is suggested that the following factors may be used to calculate the intakes of the respective nutrients from the protein intake: vitamin B₁, 1.6×10^{-6} for all children; riboflavin, 2.7×10^{-5} for children below 12 and 2.4 or 2.5×10^{-5} for girls and boys, respectively, above 12 years; nicotinic acid, 1.7×10^{-4} for all children.—D. Harvey.

4046

EPFRIGHT, E. S., RODERICK, C., SIDWELL, V. D. and SWANSON, P. P. Relationship of estimated nutrient intakes of Iowa school children to physical and biochemical measurements. *J. Nutrition*, 1954, **54**, 557-570. [Iowa Agric. Exp. Stat., Ames.]

Comparisons are made between 223 school-children whose mean intakes of energy and 8 nutrients were equal to or above U.S. National Research Council recommended allowances and 432 children in whose diets at least one nutrient was less than 67 per cent. of the allowances. The children were representative of public school children of the State of Iowa (see Abst. 3955, Vol. 25).

Children with liberal diets tended to be slightly taller and heavier and to have greater leg girth than those on the poorer diets. No significant difference in Hb or serum alkaline phosphatase was found. The mean amounts of ascorbic acid and carotenoids in serum reflected the intakes, but other influences were evident; changes with age differed for the sexes among the children with liberal intakes of these 2 substances.

The differences in nutritional status of the children in this study were small, but they are thought to indicate trends which require examination in the large groups of children whose diets, though not actually poor, may be suboptimum; their significance should be assessed further by longitudinal studies.—G. F. Garton.

4047

EPFRIGHT, E. S. and SWANSON, P. P. Distribution of calories in diets of Iowa school children. *J. Amer. Dietetic Assoc.*, 1955, **31**, 144-148. [Dept. Food Nutr., Iowa State Coll., Ames.] The data on total and percentage calories from

different food groups are based on the results of 7-day diet studies of 1188 children aged from 6 to over 18 years. Means for boys and for girls in each age group are tabulated. The percentage of calories from milk was about 20, with rather more in the younger and rather less in the older age groups. Milk, fruit and vegetables together provided 30 to 43 per cent. of the daily energy intake and these, with meat and eggs, provided 52 to 60 per cent. of calories in the mean daily diets. In respect of both number of calories and of the proportion of the total actually provided by milk, fruits and vegetables the diets which fully met the recommended dietary allowances were higher than those which failed to do so.

YOUNG, C. M., STREIB, G. F. and GREER, B. J. Food usage and food habits of older workers. *Arch. Indust. Hyg.*, 1954, **10**, 501-511. [Dept. Med. Nutr., Sch. Nutr., Cornell Univ., Ithaca, N.Y.]

Records of food eaten during 24 hr. were kept by 1439 men and 201 women aged 64 years and employed throughout the United States in 21 important occupational categories. General level of education and weekly income were also recorded. Foods were grouped in 17 classes and the adequacy of intake was judged by the criteria of Trulson *et al.* (Abst. 3893, Vol. 19).

Only 39 per cent. of men and 35 per cent. of women were taking adequate amounts of milk; more than 1/5 of the population took none. Intake of protein was below recommended amounts for 40 per cent. of the men and 51 per cent. of the women. The ranges and means for amounts of protein were, men: 25 to 156 g., 70 g.; women 8 to 94 g., 54 g. The overall intake of food was considered satisfactory for only 10 per cent. of the men and 7 per cent. of the women.

There was a relation between educational standard and the use of some important protective foods, milk, vegetables rich in vitamin C and fruits and vegetables rich in vitamin A; there was none between income and the use of meat, bread, potatoes, fruits and vegetables rich in carotene and soft drinks. Of these 2 variables education was of the greater importance.

There seemed still to be a need for encouragement of the use by industrial workers of milk, citrus fruit, tomatoes and green, leafy and yellow vegetables.—D. Harvey.

N.A. and E., July 1955

surveys in Peru. 3. Chacán and Vicos, rural communities in the Peruvian Andes. *J. Amer. Dietetic Assoc.*, 1954, 30, 1222-1230. [Dept. Nutrit., Minist. Pub. Health, Lima.]

In Chacán 43 families were studied during the rainy season, and the survey was repeated in 39 of these families after the rainy season. In Vicos 40 families were included in the first survey, which was made after the rainy season, and 37 of these were studied again during the rainy season. The methods of study were as used in a previous survey (Abst. 2269, Vol. 24). The diets contained only a small number of foods, mainly vegetable in origin, with seasonal variation in consumption of such foods as ocas (*Oxalis tuberosa* mol), ollucos (*Ollucus tuberosus*) and turnip greens.

No allowance was made for loss of nutrients in cooking. On this basis intake of ascorbic acid was adequate except in the rainy season survey at Chacán. In all surveys intake of iron, vitamin B₁ and nicotinic acid were adequate; all other nutrients were below recommended allowances.

A study of the physical status of 28 children of the families will be the subject of a separate report, but it is stated that there were signs which suggested that intakes of vitamins A and B complex, particularly riboflavin, and of protein and energy, were inadequate. (For parts 1 and 2 see Absts. 2269, Vol. 24; 2574, Vol. 25.)—F. C. Aitken.

4050

BALLETTO, G. M. A nutritional survey in the central province of Tanganyika. *East African Med. J.*, 1954, 31, 459-464. [Med. Serv., Tanganyika.]

The failure of crops after a drought in 1952-53 made it necessary to open famine camps in the Dodoma District, where maize flour and meat were issued free to the Wagogo. In September 1953 a nutritional survey was made in 3 camps where, in all, 1117 of the inmates were examined. Of those examined, the nutritional state of 278 was passed as normal. The number in a state of actual starvation was small, but there were numerous manifestations of deficiency, including pellagra and pellagra-like eruptions but not of classic severity, oedema, abnormal state of the mouth and tongue, keratomalacia and dry and scaly skin.

At the Government African School in Dodoma, 139 children aged from 7 to 12 years and 108 aged from 12 to 15 years were examined. Sixty-five children were classed as normal. A fair number were found with signs of malnutrition but none with any sign of pellagra. The badly nourished were mostly Wagogo coming from some distance outside the town. Children of other Tanganyikan tribes living in the town had a better diet.

GENERAL STUDIES: DIET PLANNING: EDUCATION

4051

ABBOTT, O. D., TOWNSEND, R. O. and FRENCH, R. B. A survey of food preferences of Florida men. *Florida Agric. Exp. Stat. Bull.* No. 500, August 1952, pp. 26. [Gainesville, Fla.]

Information was obtained by interrogation of 192 men in Florida between 17 and 20 and between 45 and 58 years of age, each age group being subdivided according to place of residence, rural or urban. Data are tabulated for their attitude to 160 foods as acceptable, not tried or disliked. Supplementary information was obtained about the method of preparation preferred for 30 commonly used vegetables and patterns of menus preferred on 2 days of the week, Sunday and Wednesday.

Preference was for foods that grew most abundantly in the State, those grown outside it having generally not been tried. Simple methods of preparation were preferred.—D. Harvey.

4052

VINIT, F. (with RACT, G.) Étude sur la consommation des produits laitiers. [The consumption of milk products.] *Bull. Inst. nat. Hyg., Paris*, 1955, 10, 129-179.

Questionnaires on the use of milk and cheese, issued by the *Union nationale des Associations Familiales* in the spring of 1953, are analysed exhaustively. There was a 50 per cent. response and the results are for 1219 families, rural and urban, in 31 departments of France, consisting of 7207 people, of whom 4668 were children.

The mean daily consumption of milk per head was 0.370 litre, in good agreement with amounts suggested as desirable in previous papers (Absts. 2701, Vol. 22; 3419, Vol. 23). Raw milk was used by 82.6 per cent. of families, pasteurised by 24.9 (some used both). Only about one-third of the children regularly drank milk at the afternoon snack. Particulars are given of the distribution of milk over the different meals and of the dishes in which it was used. The percentages disliking milk were: fathers 20.6, mothers 18.3, children 8.2. About one-quarter of the families reported digestive troubles ascribed to milk and in about half of these the doctor had advised against using it. Eighty-three per cent. of the mothers considered the family had enough milk; of those who did not, 88 per cent. said it was too dear.

The respective percentages disliking cheese were only 3.4, 4.4 and 2.4. Half the children had cheese daily and another 45 per cent. several times a week. Over 80 per cent. of mothers thought the family had enough cheese; nearly a quarter of all mothers said it was too dear. [The quantities consumed do not seem to be stated.] Preferences

for some 25 cheeses are given and methods of using cheese are analysed.

The results for both milk and cheese are further analysed according to geographical region, degree of urbanisation, occupation of father, occupation of mother, age of father and age of mother. There were great regional variations. The highest consumption of both was in Alsace, whereas in the South milk was used relatively little but much use was made of cheese. Liking for milk tended to diminish as urbanisation increased. The percentage of parents liking milk was slightly higher in those under 30 than in those between 30 and 50, after which it rose again.

Since the attitude of the family is much influenced by that of the mother, the importance of propaganda on the advantages of increased consumption of milk products and on methods of using them cannot be overrated.—W. M. Deans.

4053

MANN, I. High protein human food from de-stocking scrub animals. *Brit. Vet. J.*, 1954, 110, 491-499. [Dept. Vet. Serv., Kabete, Kenya.]

Scrub cattle in an overstocked area, Samburu, were slaughtered and provided dried meat and edible fat; the by-products were bone, liver, meat-, blood-, carcase-, and hoof-and-horn meals, dried rumen contents and hides. A more concentrated beef powder was made from the whole animal less bone, horn, hoof and intestines. The dried beef and beef powder are cheap and completely edible, keep well and are easily transported. As additions with bonemeal to maize flour they would supply animal protein and Ca, the nutrients likely to be deficient in African dietaries. Beef powder was found acceptable by patients with kwashiorkor.—A. Hepburn.

4054

MOHANTY, G. B. and ROY, A. B. Hydrolyzed fish protein from the flesh of waste fish. *Science*, 1955, 121, 41-42. [Dept. Fish., Orissa, India.]

A plea is made for the better use of waste fish, e.g., shark and ray, for the production of hydrolysed protein for use in countries where the supply of protein is inadequate. Preliminary work has shown that the preparation is inexpensive and palatable, that it contains all the essential amino-acids and that it keeps well.—J. S. Thomson.

4055

DE OLIVEIRA LEITE, J. Aproveitamento do melaço como fonte de proteínas no Brasil. [Use of yeast as a source of protein in Brazil.] *Arg. brasil. Nutrição*, 1953, 9, 101-122.

In Brazil it would cost about a third of the income of the average middle-class industrial or

commercial worker to purchase 70 g. protein daily from animal sources. The average diet in the country is one of the poorest in the world. The literature on food yeast is briefly reviewed, and it is concluded that 70 g. protein from this source could be retailed for Cruz. 1.90 against 20.00 for egg protein and 7.40 for milk (18.72 Cruz. = 1 \$). Yeast protein is an ideal supplement to diets rich in cereals. Sufficient to supply the needs of 25 million people could be produced by diverting raw materials at present used for alcohol production.—D. Dumeau.

4056

GOVIL, K. K. Consumers' trials with food yeast in Uttar Pradesh. *J. Indian Med. Assoc.*, 1954, 24, 220-223. [Provincial Hyg. Inst., Lucknow.]

Two trials of food yeast (*Torula utilis*) supplied by FAO are reported. In the first, 18 women training as midwives or health visitors had food yeast kneaded with the flour in the making of chapatis, or added to dal or vegetables after cooking. Half an ounce daily, divided between the morning and evening meals, did not affect the flavour of the food or cause digestive upset; more was unacceptable.

In the second, 21 village men were given 11 g. food yeast daily to mix with their food. Three gave it up owing to digestive upsets, the others continued it for some months. They did not gain weight, but reported better appetite and sleep. They would not have been willing to pay for it and it is considered that to create a demand, wide publicity and free supply will be necessary and that meanwhile food yeast should be incorporated into the diet of institutions, hotels and cafés.—W. M. Deans.

4057

DE SIQUEIRA, R., PECHNIK, E. and GUERNELLI, O. Pesquisas de bioquímica aplicada. [Results of applied biochemistry.] *Univ. Brasil Inst. Nutrição Trab. e Pesq.*, 1952, 5, 41-71. English summary.

The use of some oleaginous plants, wild peanuts (*Arachis nambiquarae*, L.), seeds of the rubber plant (*Hevea brasiliensis*, Mart.) and oil from these seeds as foods is discussed. (From summary.)

PLATT, B. S. Human nutrition and the sophistication of foods and feeding habits. Some observations, implications and speculations. *Brit. Med. J.*, 1955, i, 179-185. [Human Nutrit. Res. Unit, Med. Res. Council Labs., London, N.W.3.]

The observations in this paper are based on a review of the literature given at the 1954 Annual

N.A. and R., July 1955

Meeting of the British Medical Association. Treatments which may be given at different stages in food production and technology are tabulated, with indications of some possible hazards to health. The implications of sophistication considered in greatest detail are those involved in the feeding of infants on some form of cow's milk, and the speculations are on how far a reduced intake of galactose may adversely affect the process of myelination of nerves and on whether an abnormality in composition of the myelin may be the cause of disseminated sclerosis.—D. Harvey.

4059

GUERNELLI, O. Estudo sobre as possibilidades de enriquecimento da farinha de mandioca. [Possibilities of enriching manioc flour.] *Arg. brasil. Nutrição*, 1953, 9, 205-240. [Inst. Nutric., Rio de Janeiro.]

Manioc is one of the staple foods in Brazil; in 1949 12.6 million tons were grown, as against 5 million tons of maize. Production is described and tables of composition and vitamin content from the literature are reproduced. In order to bring the usual poor diet up to estimated requirements for vitamins and minerals manioc flour should be enriched with vitamin B₁, riboflavin, nicotinic acid, Fe and Ca. The costs and technical aspects of enrichment are discussed.

D. Duncan.

VAN SICKLE, A. W. and HOGAN, R. J. In-flight feeding during sustained flight of single-place jet aircraft. *J. Aviation Med.*, 1954, 25, 523-529; 555. [Turner Air Force Base, Albany, Ga.]

The problem is that of installing in the cockpit, in such manner as not to interfere with the pilot's efficiency, a readily available supply of drinking water and acceptable foods. The devices employed are described.—F. C. Aitken.

4062

SANTOS, W. J. O problema da educação alimentar no Brasil. [The problem of food education in Brazil.] *Univ. Brasil Inst. Nutrição Trab. e Pesq.*, 1952, 5, 141-186.

The difficulties of planning a campaign of nutritional education in Brazil are manifold because of the poverty, ignorance and prejudices of the people. An increase in income alone is insufficient to ensure better nutrition. Education in nutrition must be accompanied by attention to other problems of public health and of government, such as distribution and price control. Continuous action is necessary and isolated propaganda drives are of little value. National survival demands a planned policy to prevent permanent and progressive under-nutrition in the population. A National Food Organisation is called for, which can plan a wide policy and use every means to carry it through by employing a large body of workers including those in research, medicine, nursing, public health, agronomic, economic and other fields. Possible lines of attack are discussed, including those appropriate in urban and rural communities, in infant nutrition and in technical education.

WELLS, O. V. Outlook for food supplies, surplus commodities, and food habits. *J. Amer. Dietetic Assoc.*, 1955, 31, 13-17. [Agric. Marketing Serv., U.S. Dept. Agric., Washington, D.C.]

4065

PICKREL, L. and WITT, L. An exploration of possible increases in food consumption. *Quart.*

Vol. 25, No. 3

Bull. Michigan Agric. Exp. Stat., 1954, 37, 27-34. [Dept. Agric. Econ.]

The emergence of food surpluses in the United States prompted this calculation of the effect on consumption of different foods if each low-income group could be induced to adopt the consumption habits of the next higher income group. The basic data are from the 1950 census and "Food consumption of urban families in the U.S., spring 1948" (Bureau of Human Nutrition). People with incomes of \$7500 or more are ignored. The changes imagined would affect some 150 million people.

The percentage increases would be: tomatoes and citrus fruits 11.5, "other vegetables and fruit" 10.1, dairy products except butter 6.6,

meats, poultry and fish 6.2, eggs 5.1, green and yellow vegetables 4.8. The percentage decreases would be: sugar and syrups 0.6, potatoes and sweet potatoes 1.6, butter, fats and oils 3.6 (owing, apparently, to a drop in use of fat pork), flour and cereal products 4.3, beans, peas and nuts 7.6. For most foods, more than half the above increases, as well as increases in potato and sugar consumption, would be achieved by concentrating on income groups below \$3000. Some of the changes, e.g., greater use of fruit and vegetables and dairy products, might lead to improved nutrition. They would not solve the problem of surpluses immediately, except for dairy products. If, however, prices and policies were such as to encourage the use of grains to feed livestock and the growing of fruit, vegetables and feedingstuffs in place of cotton, tobacco and wheat, other surpluses would be reduced.—W. M. Deans.

SCHULZ, T. A 'human needs' diet: autumn 1954. SCHULZ, T. and FIELD, D. E. 'Human needs' diets in Northern Ireland. *Bull. Inst. Statistics Oxford*, 1954, 16, 363-369; 370-371.

The cost of a "human needs" diet in the autumn of 1954 was 62s. 6d. compared with 63s. 7d. in the spring (Abst. 1124, Vol. 25), but the diets were not identical, eggs and fish having been largely replaced by boiling bacon and cheese. A diagram shows the trends of the index of retail prices of food of the London and Cambridge Economic Bulletin and of the cost of the "human needs" diets since 1941; the latter was always higher but the difference between them is tending to level out.

The cost of a "human needs" diet in Belfast, modified to suit local habits, e.g., including more potatoes and bread ["vegetables" in line 3 seems to be a misprint] than in the English diets, was 62s. 2½d. in spring and 59s. 6d. in autumn 1954.

W. M. Deans.

4067

MULDER, T. Het vetverbruik in Nederland. [Fat consumption in the Netherlands.] *Voeding*, 1954, 15, 542-544.

The annual report for the Ministry of Agriculture, Fishery and Food gives data for fat consumption in the Netherlands. From it the following conclusions are drawn:

1. There is a tendency to higher fat consumption, chiefly from increased amounts of "visible" fats, as butter or margarine.

2. Visible fats constitute roughly 60 per cent. of total fat consumed. Before the war this proportion was somewhat less.

3. Milk and cheese, providing about 17 per cent. of total fat, supply the greater part of the invisible fats consumed.

4. Before the war butter accounted for 12 or 13 per cent. of total fat; now it provides only 5 per cent. The figures for margarine are 15 per cent. before the war and 35 per cent. now.

FOX, F. W. Agricultural foundations of nutrition. 11. Native reserves and locations. *S. African Med. J.*, 1953, 29, 63-66. [*S. African Inst. Med. Res.*, Johannesburg.]

For parts 8, 9 and 10 see Abst. 2612, Vol. 25. Some basic data are tabulated showing that the people in the Reserves depend for about half their cereal requirements on purchases from European farmers. These Reserves, 5 in number with 4 million inhabitants, occupy only 13 per cent. of the total area of the Union, which has an average annual rainfall of 17½ in., but only 2 of the Reserves have an average rainfall less than 25 in. and 2 have more than 30 in. Work by the Department of Native Affairs and by the African National Soil Conservation Association is mentioned in attempts to relieve the serious mismanagement of the soil.

GENERAL STUDIES

4070

TOMPKINS, W. T., WIEHL, D. G. and MITCHELL, R. M. The underweight patient as an increased obstetric hazard. *Amer. J. Obstet. Gynecol.*, 1955, 69, 114-123. [*Nutrit. Res. Clin.*, Pennsylvania Hosp. (Philadelphia Lying-In Hosp.)]

Hospital patients whose reported pre-gravid weight-for-height ratio was considerably below or considerably above medico-actuarial standards had an increased chance of developing toxæmia. The risk of prematurity, with birthweight 5½ lb.

N.A. and R., July 1955

or less, decreased as pre-gravid weight-for-height increased. A curve shows the average cumulative gain in weight during pregnancy of clinically normal patients whose pre-gravid weight-for-height was within 10 per cent. of the standard. The incidence of toxæmia or of toxic signs appeared to increase if the weight gain in pregnancy deviated much above or below the "normal" gain during the second trimester, or if there was an excessive gain during the third trimester. Smaller weight gains during pregnancy were associated with increased incidence of prematurity. Babies of underweight mothers were lighter and shorter than babies of mothers of approximately standard weight at the beginning of pregnancy. But consideration of "net gains" by mothers of differing pre-gravid weights suggested that although failure to gain an average amount, especially in the first two trimesters, increases the likelihood of prematurity, greater gains have little effect, if any, on the size of the baby.—A. M. Thomson.

NELSON, T. R. A clinical study of pre-eclampsia. 1. 2. *J. Obstet. Gynaecol. Brit. Empire*, 1955, 62, 48-57; 58-66. [Maternity Hosp., Aberdeen.]

1. The difficulties of precise description are discussed and a definition based primarily on an increase in diastolic blood pressure to 90 mm. or more after the 26th week of pregnancy is adopted. It is regarded as severe when albuminuria is appreciable, $\frac{1}{2}$ part per 1000 by Esbach's scale. Among booked primigravidae at Aberdeen Maternity Hospital the incidence of severe pre-eclampsia did not increase very much with age, but after the age of 30 that of mild pre-eclampsia increased greatly. This may be due to a tendency to hypertension latent in older women. No gradient by maternal social class or by height was found. Excessive weight gain between 20 and 30 weeks was associated with a higher risk of both mild and severe pre-eclampsia, but not of severe pre-eclampsia in mothers aged over 30 years. It is concluded that the relation between gain in weight and pre-eclampsia, particularly the severe grade, is too indefinite to be of real value in predicting the development of pre-eclampsia and that dietary control is, in fact, unlikely to benefit those who most require help.

2. The incidence of and mortality from eclampsia in primigravidae booked at hospital are discussed. In 69 cases of eclampsia among booked patients there were 10 stillbirths and 5 neonatal deaths in the first week; in all cases of death the previous pre-eclampsia had been severe. In severe pre-eclampsia without fits the foetal mortality rose with maternal age and with declining social status, but the effect of these on the incidence of severe

pre-eclampsia was small. The stillbirth rate per 1000 births in severe pre-eclampsia in booked primiparae fell from about 150 in 1938 to 1942 to under 30 in 1951 to 1953. This was due probably to better antenatal care and better treatment of pre-eclampsia, as well as general improvement in maternal health resulting from higher standards of living and better nutrition. The prognosis for the foetus is unlikely to be further improved by present lines of medical treatment; it might be improved by better maternal health and physique and by a decrease in the proportion of primigravidae over 30 years of age.—A. M. Thomson.

[Morbidity and mortality at the Clinic for children's diseases in Trieste in the ten years 1944-53.] *Lattante*, 1954, 25, 454-465. [Clin. Malatie Bambini, Osp. Riuniti, Trieste.] English summary.

The Clinic deals only with children under 2 years of age.

Very little information is given about nutritional disease. Of 5826 children received at the Clinic between 1944 and 1953, 1287 were suffering from acute nutritional disturbance, whether infective or not, and 601 from dystrophy. The annual number of cases has remained fairly constant with a maximum in 1944, when food conditions were worst, but the proportion of deaths has steadily declined.

RUSO, G. Alcune considerazioni sulle cause di morte prima e dopo 50 anni di età. [Causes of death before and after 50 years of age.] *Rend. Ist. Super. Sanità, Rome*, 1954, 17, 302-325. French, English and German summaries.

Mortality in Italy fell from 14.5 per thousand in 1931-33 to 10.7 per thousand in 1947-49. Deaths before 50 years of age fell by 41 per cent., those after 50 by 18 per cent. The only causes of death which increased in frequency were tumours and diseases of the circulatory system, at all ages, and diseases of the blood and blood-forming organs in the older group.

Causes of death before 50, in order of incidence, were infective and parasitic diseases, diseases of the digestive system, diseases of the respiratory system, diseases of infancy, and violent or accidental deaths; the percentage from other causes was negligible. In the older group the most significant causes were diseases of the circulatory system, diseases of the nervous system and sense organs, tumours, senility and old age, and diseases of the respiratory system.—D. Duncan.

JELLIFFE, D. B., BRAS, G. and STUART, K. L. The clinical picture of veno-occlusive disease

of the liver in Jamaican children. *Ann. Trop. Med. Parasitol.*, 1954, 48, 386-396. [Dept. Med., Univ. Coll. W. Indies, Jamaica.]

From a study of 11 children who had the disease clinical details are given for the acute form, 5 cases, and for the sub-acute form, 2 cases; in the remaining 4 the disease was chronic, in which form it can be diagnosed only by liver biopsy or at post mortem. Histological changes have already been described (Abst. 1134, Vol. 25), and the present cases are discussed in their relation to scrous hepatosis, Chiari's syndrome, Senecio poisoning and Indian infantile cirrhosis. The etiology is thought not to be primarily nutritional. It may result from the action of a bacterial toxin, and reference is again made to its possible association with the use of "bush teas" (see Title 5146, Vol. 24).—D. Harvey.

LIE KIAN JOE and SUTOMO TJOKRONEGORO. Hepatic fibrosis or cirrhosis in children in Djakarta. *Doc. Med. geogr. trop.*, 1954, 6, 193-207. [Inst. Pathol., Sch. Med., Univ. Indonesia, Djakarta.]

Needle biopsies were made on the livers of children in the Paediatric Department of the Central Hospital in Djakarta. Of the children examined, from 2 months to 10 years of age and with malnutrition and signs of protein deficiency, 100 were Indonesians and 4 Chinese. The most important anomalies found were fatty liver, cellular infiltration of the portal spaces, and proliferation of connective tissue. Biopsies were made also on 45 Indonesian and 12 Chinese children from 17 days to 13 years of age and without signs of malnutrition. The same changes in the liver were found as in the children with malnutrition, fibrosis being not infrequent. Case histories are given. It is suggested that viral hepatitis may be a contributory cause of liver fibrosis.

VENKATACHALAM, P. S., SRIKANTIA, S. G. and GOPALAN, C. Clinical features of nutritional oedema syndrome in children. *Indian J. Med. Res.*, 1954, 42, 555-568. [Nutrit. Res. Labs., Indian Council Med. Res., Coonoor, S. India.]

The descriptions are based on 207 cases seen over 4 years. The age incidence differs from findings reported from elsewhere, nearly half of the patients having been over 3 years of age when first seen. They came from very poor surroundings, for their "average daily family income was one rupee" and a dietary survey of 30 patients showed that daily intakes of energy, about 105 Cal., and of protein, about 2.2 g., each per kg. bodyweight, were low. The peak period of seasonal incidence was in April and May, the "fly season", when the incidence of infective diarrhoea is also at its maximum.

The clinical findings are described under the headings; growth, oedema, facies, skin changes, hair changes, gastro-intestinal disturbances, liver enlargement, signs of vitamin deficiency, haematology and plasma protein levels. The minimum diagnostic criteria are failure of growth and decrease of blood plasma proteins. These are

often accompanied by one or more of the other signs, from diarrhoea present in 61 per cent. and skin lesions in 39 per cent. to liver enlargement, moderate in 10 and gross in 5 per cent. of all cases. Treatment was with reconstituted skimmed milk.

In prognosis the fatal cases were usually those in which apathy was most intense. The mortality rate was about 10 per cent. Relapses occurred in 8.5 per cent. of the patients and were not related to the intensity of the earlier attacks.

Surprisingly, in some children who went back to the same diet no relapse occurred.—D. Harvey.

4089

BRAS, G. and CLEARKIN, K. P. Histopathology of the pancreas in Jamaican infants and children. *Doc. Med. geogr. trop.*, 1954, 6, 327-330. [Dept. Pathol., Univ. Coll. West Indies, Jamaica.]

The state of the pancreas in Jamaican children with signs of protein malnutrition was investigated. Material was obtained from 49 children under 11 years of age. The changes were listed as atrophy, degeneration of acinar cells, dilatation of ducts, apparent increase in intercalated ducts, diffuse fibrosis and delayed development. Of 2 groups of children, 10 with kwashiorkor and 5 with marasmus, only 1 in each group showed no pancreatic change. Of 33 miscellaneous cases, 22 had fatty liver and of those 15 had pancreatic changes also. Eleven of the miscellaneous cases were without fatty liver, and only 2 of them had slight pancreatic changes. The fat in the liver of the miscellaneous cases was not distributed in quite the same way as in kwashiorkor, but the correlation between the presence of fatty liver and of pancreatic changes was high. The children with kwashiorkor or marasmus were more severely undernourished and underweight than the miscellaneous group, but the findings are not considered as support for the view that the miscellaneous cases with fatty changes in the liver represent a pre-clinical stage of kwashiorkor.

4090

WILCOX, E. B., GALLOWAY, L. S., WOOD, P. and MANGELSON, F. L. Children with and without rheumatic fever. 3. Blood serum vitamins and phosphatase data. *J. Amer. Dietetic Assoc.*, 1954, 30, 1231-1238. [Dept. Foods Nutrit., Utah State Agric. Coll., Logan.]

The children, 131 with a history of rheumatic fever and 131 without, had been the subjects of previous studies (Abst. 5090, Vol. 24).⁸ vitamin A, carotene, ascorbic acid, riboflavin, phosphatase and cholesterol were estimated. Differences between the groups appear of little nutritional significance.—F. C. A.

4091

GOPALAN, C., SRIKANTIAH, S. G. and VENKATACHALAM, P. S. **Electrocardiographic changes in severe malnutrition.** *Indian J. Med. Res.*, 1955, 43, 15-21. [Nutrit. Res. Labs., Indian Council. Med. Res., Coonoor.]

On admission the 31 children had heart rates of 75 to 172 per min., and bradycardia was present in 4; this sign has not been described in kwashiorkor. Tachycardia, which has been described in kwashiorkor, was present in 7.

Two subjects showed sinus arrhythmia. A child which died the day after admission showed sinus arrest for one cardiac cycle in every 3 or 4. An adult showed an irregular rate of 50 with "wandering" of the pacemaker and another showed an inverted P wave but a normal PR interval. All the irregularities disappeared after treatment.

In 15 out of 16 adults and 3 out of 10 children more fully studied the QT interval was prolonged, and it remained so in those studied after treatment. The children affected had bradycardia or normal heart rates.

In all there were 36 adults with severe malnutrition, including 16 with oedema, and 31 children aged 1 to 5 years, including 10 with nutritional oedema syndrome, which in 2 resembled kwashiorkor. Electrocardiograms were taken on admission to hospital, and in 6 adults and 6 children were repeated about 40 days later, when recovery was still incomplete.

In the 36 adults, heart rates on admission varied from 44 to 92 per min., with 12 below 60, and there was no correlation with clinical severity of the low blood pressure or degree of anaemia. Of the 6 subjects re-examined later 5 showed an average increase in heart rate of 30 per cent.; the other was unchanged at 75.

In all the subjects there was reduced amplitude of P waves, QRS complexes and T waves; all amplitudes increased after treatment.

The causes of the changes are discussed.

REH, E., CASTELLANOS, A. and DE RUEDA, Y. B. **Estudio de la dieta y de las condiciones de vida existentes entre los trabajadores de una plantacion azucarera de Guatemala.** [Study of the diet and living conditions of workers on a sugar plantation in Guatemala.] *Bol. Ofic. sanit. panamer.*, 1954, 37, 32-52. [Inst. Nutric. Centro America y Panama, Guatemala.] English summary.

A study of 91 sugar-plantation workers and their families showed that they had a low wage and a very low standard of living for food, clothing and other primary needs. Mortality rates for infants and young children were high. Most children and young adults were underweight even when their

small stature was allowed for. Expenditure on food was low and the diet consisted mainly of maize with a little wheat and rice, some fruit and vegetables and very little meat, fish or milk. The chief deficiencies appeared to be of animal protein, vitamin A and riboflavin. Although the intake of vitamin C seemed low, the serum ascorbic acid values showed that there was no lack of the vitamin. Clinical examination revealed many people with dry skin and follicular hyperkeratosis, occasional angular stomatitis and vascularisation of the conjunctiva. Dental caries, goitre, anaemia and malaria were fairly common, and most of the subjects had intestinal parasites.

Some general suggestions for improving the economic situation, living conditions and diet are made.—A. M. Copping.

4093

BIERDRAGER, J. and DE ROOK, H. **Health conditions in Netherlands New Guinea.** *Doc. Med. geogr. trop.*, 1954, 6, 252-266. [Health Dept., Netherlands New Guinea Petroleum Co.]

Only a small part of the report is concerned with dietary disease. The staple foods of the Papuans are sago, taro, ketella (manioc, *Manihot utilissima*), sweet potatoes and yams, with the products of hunting, shellfish, molluscs, and fruits. It was found in 1947 that the diet contained 0.7 mg. vitamin B₁ per 1000 Cal., but in artificial communities beriberi is frequent. On the estates polished rice is the staple diet. Katjang idju beans are used to supplement it, but they are not popular, so $\frac{1}{2}$ kg. rice (Roche mix, Hofmann-La Roche, Basle) fortified to contain 200 times the normal content of vitamin B₁ has been added to 100 kg. polished rice. Where this has been done beriberi has not occurred. Scurvy is not found among the Papuans. New Guinea sore mouth has been observed on estates and in villages in Australian New Guinea. It is characterised by bleeding and ulceration of the gums, cheeks and palate. It heals when fresh vegetables are used. Goitre is endemic in certain parts of the highlands in Australian and Netherlands New Guinea.

Vitamin A

4094

MOSCHETTE, D. S. **Metabolic studies with pre-adolescent girls. 1. Utilization of carotene.** *J. Amer. Dietetic Assoc.*, 1955, 31, 37-44. [Dept. Home Econ., Louisiana Agric. Exp. Stat., Louisiana State Univ., Baton Rouge.]

The utilisation of carotene from boiled, mashed sweet potatoes in diets with and without the addition of fat-free milk was studied in 6 girls aged from 8 to 11 years. During a preliminary period of 6 weeks on unrestricted diet, Hb values and carotene,

N.A. and R., July 1955

vitamin A and ascorbic acid in the serum were estimated. For the ensuing 9 weeks the girls were given a basal diet providing all the U.S. National Research Council's recommended allowances except for vitamin A. The diet was supplemented during two fortnights of the period with sweet potatoes calculated to provide 3600 μg . β -carotene daily. The amount of carotene excreted daily in the faeces ranged from 61 to 78, with mean 71.1, per cent. of the dose. Variation was considerable in individual subjects, but was less in a later experimental period after a second basal period. The average value for carotene in the serum during the preliminary period was 162 μg . per 100 ml. There was a decided fall to an average value of 94.0 during the first basal period when no carotene was given, and a rise, which was not statistically significant, to 105.6 when sweet potatoes were added to the basal diet. The average serum value for vitamin A during the first basal period was 44.1 μg . per 100 ml., which was higher than the value of 28.8 during the preliminary period. Addition of sweet potatoes did not increase the value. The observations made during the second basal and experimental periods showed the trends to be similar. Addition of fat-free milk to the diets did not significantly influence the serum values for carotene or vitamin A.

ASCHER, K. W. Study of 22 malnourished patients with Bitot's spots. *Amer. J. Ophthalmol.*, 1954, 38, 367-373. [5 West Fourth St. (2), Cincinnati, Ohio.]

Of 642 patients with definite or suspected vitamin deficiency, examined in the Nutrition Clinic of Hillman Hospital, Birmingham, Ala., 22 had Bitot's spots, and were studied for periods ranging from a few days to 58 weeks in 1940 and 1941. Only 3 complained of hemeralopia and there was no other sign of vitamin A deficiency. The diet

had been very inadequate. The diagnosis of deficiency given was vitamin B, once, riboflavin 8 times, nicotinic acid 11 times, subclinical 4 cases, and doubtful 4 cases. The Bitot's spots are described in detail. Administration of riboflavin or of a mixture of B vitamins had no effect on them. The proportionate distribution of deficiencies, as diagnosed above, was much the same among the whole group of 642 patients as among the 22 with Bitot's spots. It is considered that dietary deficiency predisposes to formation of Bitot's spots but that the nature of the deficiency is uncertain.—E. M. Hume.

4098

HOOF, C. Acute hypervitaminose-A. [Acute vitamin A excess.] *Maandschr. Kindergeneesk.*, 1954, 22, 271-279. French and English summaries.

Bulging of the anterior fontanelle was observed in 4 breast-fed infants, from 4 to 5½ months old, within a day or so after administration of a single dose of 100,000 or 200,000 I.U. vitamin A accompanied by a large dose of vitamin D. There was no other sign of abnormality and the appearance of the fontanelle was normal again within 48 hr.

In a search of the literature reports were found of 24 other cases.—E. M. Hume.

HERR, M. Über die Häufigkeit von Kraniotabes in Bruck a.d. Mur und Umgebung. [Incidence of craniotabes in Bruck a.d. Mur and its neighbourhood.] *Öst. Ztschr. Kinderheilk.*, 1954, 10, 251-254. [Bruck a.d. Mur.]

The suggestion to fortify milk with vitamin D received support from the discovery in Bruck of a child with severe rachitic deformities. Scrutiny of the records for 380 infants from 2 to 7 months old, examined between October 1951 and September 1952, showed 151 (39.7 per cent.) free from craniotabes. The percentage with slight craniotabes was 31.2, moderate 24, and severe 5.1. The incidence was highest at the age of from 4 to 6 months, and in the months December to February, but even in summer over 40 per cent. were affected. Fortification of the whole milk supply with vitamin D is recommended with the use of large doses of the vitamin for newborn infants, the risk of injury being borne in mind.

SNAPPER, I., SEELY, R., FALK, S. and FEDER, I.
Osteomalacia in New York. *Ann. Int. Med.*,
 1954, **41**, 893-909. [Brooklyn, N.Y.]

Four cases of osteomalacia are described in patients attending hospitals in New York. All the patients suffered from some form of fatty diarrhoea which prevented the absorption of vitamin D. The bone lesions were treated by intramuscular injection of vitamin D with or without ultraviolet light.—E. M. Hume.

4102

HANSEN, F. and RÖSSIGER, S. Phosphataseaktivität und Rachitis bei Keuchhusten. [**Phosphatase activity and rickets in whooping-cough.**] *Ztschr. Kinderheilk.*, 1954, **75**, 565-570. [Kinderklin., Med. Akad., Düsseldorf.]

Since whooping-cough is complicated by the presence of rickets, it was desired to find an objective means of appraising changes in the rachitic state in the course of whooping-cough. The behaviour of the alkaline phosphatase of the blood was therefore investigated. It was estimated by the method of Jenner and Kay (Abst. 17, Vol. 2) at intervals of 14 days in 7 patients with whooping-cough 4 times, in 17 three times, in 4 twice, and in 3 once. For the ages from 1 month to 15 years values from 8.1 to 9.7 units of Jenner and Kay were taken as normal. The range of values in the patients was very great. When all the values were plotted against the duration of the disease in weeks, the curve representing the mean for each week fell slightly at first, from 10.1 to 9.5 after 4 weeks, then rose to 11.3 after 6 weeks, and to nearly 12 after 9 weeks. The values were lower in the older children. In uncomplicated whooping-cough without rickets, the phosphatase value fell steadily for the first 4 weeks; the severity of the cough then began to decrease, and the phosphatase value began to rise and continued to do so. In whooping-cough with rickets the values were all higher than without it, but the lowest values occurred in the same way after 4 weeks.

Since the phosphatase value was affected by whooping-cough, it could not be used as a criterion for the presence of rickets in whooping-cough. It is suggested that the unfavourable effect of whooping-cough on rickets is due to its unfavourable effect on serum alkaline phosphatase.

4103

ZETTERSTRÖM, R. and WINBERG, J. **Primary vitamin D refractory rickets. 2. Metabolic studies during treatment with massive doses of vitamin D.** *Acta paedint.*, 1955, **44**, 45-61. [P. edist. Clin., Karolinska Sjukhuset, Stock-

holm.] French, German and Spanish summaries.

Metabolic studies are reported on 2 patients with rickets refractory to vitamin D (Abst. 1175, Vol. 25). The children were maintained for most of the studies on a diet supplying daily 2 g. Ca and 2 g. P, or occasionally 0.1 g. Ca and 0.9 g. P. Vitamin D₂ or occasionally vitamin D₃ was given orally in oil. Ca and P were estimated in the blood serum, urine and faeces for periods of 6 days. Before any treatment was given the serum P value tended to be low but fluctuated rather widely. The absorption of P from the gut was satisfactory but the bulk of it was excreted in the urine despite the low serum value. The phenomenon could not have been due to failure of re-absorption by the kidney tubules, since a decrease in absorption was followed by a decrease in urinary excretion though the serum value was unchanged. The serum Ca value was normal or low; absorption from the gut and urinary excretion were very low. No vitamin D had been given previously for from 4 to 6 months.

Vitamin D was given at first in small doses [amounts not stated], increasing progressively. There was an immediate fall in serum P but urinary P remained fairly constant. There was a fall also in serum Ca. Absorption of Ca increased in one patient but not in the other. With continued treatment and larger doses of vitamin D, the serum P value rose above the normal but the amount excreted in the urine was scarcely increased, suggesting that renal tubular re-absorption had increased. There was increased retention of P in one child but not in the other. The serum Ca value rose in both children but retention was increased only in the same child as for P.

With doses of from 3 million to 5 million I.U. vitamin D daily for more than a month, no sign of toxicity appeared in 1 child though the serum Ca value rose above the normal, but the output of Ca in the urine was very small. In the second child the value for serum P rose above normal and for serum Ca far above normal, and the urinary output of Ca was very large, beginning to increase before the increase in the serum.

With intravenously injected, labelled P, in one child, the serum value for P decreased much more slowly, and the amount in the urine was less, after treatment with vitamin D than before.

Measurement of alkaline phosphatase seemed the most delicate method of assessing the efficacy of treatment.

In these metabolic studies it was not possible to demonstrate that the response to massive doses of vitamin D in refractory rickets differed significantly from the response to physiological doses in ordinary rickets, except that there was an initial fall in the serum P value. The studies of

N.A. and R., July 1955

P metabolism did not yield evidence of a primary defect in renal tubular re-absorption. Some defect is presumed in the physiological processes regulating mineralisation, but its nature remains conjectural.—E. M. Hume.

YENDT, E. R., CONNOR, T. B. and HOWARD, J. E. **In vitro calcification of rachitic rat cartilage in normal and pathological human sera with some observations on the pathogenesis of renal rickets.** *Bull. Johns Hopkins Hosp.*, 1955, **96**, 1-19. [Dept. Med., Sch. Med., Johns Hopkins Univ., Baltimore, Md.]

Young rats from 3 to 4 weeks old were fed for from 20 to 30 days on a rachitogenic diet low in P, after which they were killed and longitudinal slices were cut from the head of the tibia to include the epiphysis and a small part of the shaft. Slices were tested with silver nitrate, and bones showing healing or too little rickets were rejected. Slices from suitable bones were placed in flasks in the samples of human serum to be tested or in a mixture of inorganic salts; pH was adjusted to between 7.30 and 7.50 by shaking in 5 per cent. CO₂ and 95 per cent. O₂. The flasks were incubated with shaking for 24 hr. at 37.5° C. The slices were then fixed in alcohol and stained with silver nitrate. Calcification was assessed by an arbitrary scale having 5 degrees. Estimations were made of Ca, P, Mg and alkaline phosphatase, and of ultrafiltrable Ca and P, on the same samples of serum. In the latter half of the investigation, the lowest value for the product of Ca and P which would promote calcification of the bone slices in inorganic salt mixtures was determined.

For 30 patients without renal insufficiency, the product of the values for ultrafiltrable Ca and P was 33 or less in 11, and rachitic cartilage did not calcify in any of the samples. In the remainder the product was 34 or more, and calcification occurred in all but 2 which had products of 36 and 37. In 19 patients with chronic renal insufficiency, the product was 35 or more in all but 2, but calcification occurred in only 8, and did not usually do so unless the product was over 55. The ability to calcify did not seem to be related to the severity of renal insufficiency. Ten patients had milder renal insufficiency often accompanied by hypercalcaemia. The product was over 35 in all but one serum, which calcified with a product of 17; 6 others calcified and 3 failed to do so. Control experiments, in which the concentration of Ca and P was determined at which companion slices of cartilage would calcify in an inorganic salt solution, failed to show any inherent defect in capacity to calcify.

The value for Mg in the serum of 23 patients without renal insufficiency was at or below 2.8

mg. per 100 ml.; in 18 with chronic renal disease it was over 2.8 in all but 6. Mg is known to have an inhibiting effect on calcification. Serum from some subjects suffering from the effects of excess of vitamin D or dihydrotachysterol did not fail to calcify cartilage. The various known abnormalities in the serum composition of patients with renal insufficiency are discussed as possible influences inhibiting calcification, and all are rejected except the raised Mg value which is considered as possibly contributory. The failure to calcify in renal insufficiency is accepted as proved but the mechanism is held to be still unknown.—E. M. Hume.

HUISMAN, T. H. J. **Amino-zuurscheiding en vitamine-deficiënties. [Excretion of amino-acids in vitamin deficiency.]** *Voeding*, 1954, **15**, 527-542. [Kinderklin., Alg. Prov. Ziekenhuis, Groningen.]

Improved methods for separating amino-acids in urine are discussed; total amounts of amino-acids in normal adults vary between 750 and 2000 mg. per 24 hr., approximately 1 per cent. of total N output. The same amounts were found in normal children on normal diet, whose ages ranged from $\frac{1}{2}$ to 13 years, and who were under observation in hospital for an unspecified period. The effect on amino-acid output of variations in the intake of protein and fluid were negligible. In 4 children with signs of scurvy the loss of amino-acids was higher than in normal children in both quantity and percentage of total N output, the latter being 1.65 instead of 1.05 per cent. Blood plasma values were normal. It was concluded that in scurvy re-absorption of amino-acids by the renal tubules is reduced. The same defect causes amino-aciduria in rickets, which has been fully described in a previous report (Abst. 2280, Vol. 23).

It is considered that other vitamin deficiencies probably cause loss of amino-acids, and that further tests are needed to prove the renal origin. In vitamin D deficiency increased loss was found of threonine, serine, glycine, histidine, lysine and glutamic acid in bound form; in vitamin C deficiency there was increased output of tyrosine and possibly of phenylalanine also.—M. Eddison.

MARCUSSEN, P. V. **Tuberculous and tuberculous complications during treatment of lupus vulgaris with calciferol.** *Danish Med. Bull.*, 1954, **1**, 165-171. [Dermatol. Dept., Finsen Inst.]

It was sought to check the impression that

activation of other tubercular foci is liable to occur during treatment of lupus with vitamin D.

Of 248 patients under treatment for lupus with vitamin D, there was re-activation of old tubercular foci, including the lungs, in 6 and appearance of fresh tuberculoid processes in 37. Activation tended to occur as the lupus was healing, but did not seem to depend on the total dose of vitamin D. The complications usually disappeared again spontaneously, but a warning is uttered that preventive treatment with drugs and antibiotics should be given during the vitamin D treatment.

E. M. Hume.

4108

RUSSELL, B. The history of lupus vulgaris: its recognition, nature, treatment and prevention. *Proc. Roy. Soc. Med.*, 1955, 48, 127-132. [Skin Dept., London Hosp.]

A short article, with references, deals mainly with treatments which have been suggested for lupus vulgaris. They include, for external use, strongly caustic substances, Finsen's ultraviolet lamp and X-rays, and, for internal use, large doses of cod liver oil, calciferol and isoniazid. The incidence of lupus is stated to be only about a tenth of what it was 30 years ago, a change attributed to pasteurisation of milk and better general nutrition and hygiene.—W. M. Deans.

SCHUCHARD, W. Die Behandlung der Alopecia areata und des dyshidrotischen Ekzems mit milchweißgebundenem Vitamin D₂. [Treatment of alopecia areata and dry eczema with vitamin D₂ combined with milk protein.] *Deutsch. med. Wochenschr.*, 1955, 80, 417-418. [Marburg a.d. Lahn.]

Alopecia areata was successfully treated in 35 adults by administering twice daily a tablet containing 1 mg. vitamin D₂ combined with milk protein. Hair began to grow after from 40 to 60 tablets had been taken, and the dose was then reduced to 1 tablet daily till the hair growth was normal again.

The same result was achieved with 2 children of 7 and 8 years old, and the same treatment gave promising results with dry eczema of the hands in 10 patients.

No effect of overdosage was seen.—E. M. Hume.

FERGUSON, M. E., BRIDGEFORTH, E. B., QUAIFF, M. L., MARTIN, M. P., CANNON, R. O., MCGANITY, W. J., NEWBILL, J. A. and DABRY, W. J. The Vanderbilt cooperative study of maternal and infant nutrition. 7. Tocopherol in relation to pregnancy. *J. Nutrition*, 1955, 55, 305-321. [Div. Nutrit., Sch. Med., Vanderbilt Univ., Nashville, Tenn.]

For Parts 5 and 6 see Abst. 5103, Vol. 24.

Single estimations were made of the tocopherol content of the plasma of 1575 women. A separate group of 39 women had serial estimations of plasma tocopherol made during pregnancy and 6 weeks after. The average tocopherol content rose from 0.89 mg. per 100 ml. during the first trimester of pregnancy to 1.40 after 33 weeks. Calculations of the dietary intake of 197 pregnant women gave an average of 10 mg. daily, individual values ranging from 2.9 to 33.3 mg. Tocopherol levels in the blood generally rose with increasing age of the subject. Higher levels were found also in the few cases of diabetes examined. Levels tended to be lower in the plasma when the calculated intakes were less than 8.0 mg. tocopherol daily; in the first trimester an average of 1.06 mg. per 100 ml. was obtained with subjects receiving over 8.0 mg. but only 0.97 with those whose daily intake was less than this amount. Corresponding values for the second trimester were 1.10 and 1.02 mg., respectively, and for the third trimester 1.28 and 1.18 mg. Some association was also found between the levels of carotene in the blood and the corresponding tocopherol values. It is concluded that variation of the tocopherol content of the plasma cannot account for the complications of pregnancy which were encountered in the "normal" obstetrical population investigated.

HURLEY, K. E. and WILLIAMS, R. J. Urinary amino acids, creatinine and phosphate in muscular dystrophy. *Arch. Biochem. Biophys.*, 1955, 54, 384-391. [Biochem. Inst., Univ. Texas, Austin.]

Urine was collected on four consecutive mornings from 20 normal male subjects and 18 male subjects suffering from muscular dystrophy. The urine was analysed for creatinine, phosphate, glycine, alanine, serine, threonine, valine, leucine, citrulline and taurine; amounts are expressed as μg . per ml. urine divided by the figure formed by the second and third decimals of the sp. gr. of the urine. Creatinine and phosphate values in the normal group were 119 and 65.9, compared with 38 and 37.6 for those with muscular dystrophy. Values for leucine and valine were 1.63 and 1.97 for the normal and 2.5 and 3.4 for the dystrophic

N.A. and R., July 1955

subjects. Threonine and valine excretion appeared to be slightly raised in the dystrophic group but the differences were significant only at the 10 per cent. level. There appeared to be no significance in the differences in excretion of the other amino-acids. With increasing age the excretion of leucine, valine and taurine tended to increase in dystrophic and to decrease in normal subjects. Arginine was found in the urine of 7 of the normal and 14 of the dystrophic subjects.

HRUBÁ, F. Saturační testy k určování vitaminů v klinice i v terénu. [Saturation tests for estimating vitamin status in the clinic and in the field.] *Sborn. pathofysiol. tráv.*, 1954, 8, 154-159. [Human Nutrit. Res. Inst., Prague.] English and Russian summaries.

A report is made of studies of nutritional status in some Czech regions with regard to vitamins C and B₁ and riboflavin. Four-hr. saturation tests, which could be made simultaneously, are proposed for work in the field.

M. Prokšová (Czechoslovakia).

4114

ORSINI, M. and CAMPEA, L. La cocarbossilasi nelle sindromi chetonemiche dell'infanzia spontanea e provocate. [Cocarboxylase in spontaneous and induced ketonaemia of children.] *Arch. ital. Pediat. Puericoll.*, 1955, 17, 3-33. [Int. Clin. Pediat., Univ. Rome.] French, English and German summaries.

Ketone bodies were estimated by the method of Krainick (Abst. 28, Vol. 8) in the blood of 18 patients aged from 9 months to 13 years before, and for up to 5 hr. after, a single intravenous injection of from 20 to 100 mg. cocarboxylase. The children fasted for from 10 to 12 hr. before and during the experiment. Ketones were estimated also in the urine. Blood values for 10 normal subjects ranged from 0.70 to 2.30 mg. per cent. The values for the patients before injection of cocarboxylase ranged from 4.4 to 32.4 mg. per cent.; 3 of them had cyclical vomiting, 2 had diabetic ketosis, 2 had ketosis induced experimentally by dietary means, and 11 had ketosis secondary to other conditions. After injection of cocarboxylase, there was a definite decrease of the blood ketone values in 11 of the patients and a slight decrease in 20 others, but the reduction lasted only an hour or two, and no group was consistently affected except the two diabetics, who showed no reduction but a rise. It is concluded that cocarboxylase is likely to be of lasting use in ketosis only when there is a specific deficiency of vitamin B₁.—E. M. Hume.

POSTIGLIONE, F. and DELLA CORTE, L. Influenza della vitamina B₁ sulla sierodiagnosi di Wassermann e sulle flocculazioni per la luc. [Influence of vitamin B₁ on the Wassermann reaction and flocculation test in syphilis.] *Bol. Soc. ital. Biol. sper.*, 1954, 30, 189-191. [Ist. Semeiotica Med., Univ. Naples.]

Vitamin B₁ hydrochloride was given by intramuscular injection in a daily dose of 100 mg. for 10 days to 4 patients with confirmed syphilis, and for 30 days to 2. Six others received 500 mg. orally for from 10 to 40 days. In one patient only, whose reaction was in any case slight, was there any reduction on treatment with vitamin B₁ in the intensity of the Wassermann or Kahn reaction. There was slight increase in the sedimentation rate and no consistent effect on the concentration of albumin and globulin in the blood (cf. Abst. 5001, Vol. 23).—E. M. Hume.

4117

BARAZZONE, J. and LAMBELET, F. Accidents mortels après injection de thiamine (vitamin B₁). [Fatalities after injection of thiamine (vitamin B₁).] *Presse méd.*, 1954, 62, 1867-1868. [Clin. Thérap., Univ. Geneva.]

Cases reported in the literature of death after treatment with vitamin B₁ are reviewed and 2 such fatalities, one after intramuscular, the other after intravenous, injection of 100 mg. vitamin B₁ hydrochloride, are described. Possible causes are considered but none is thought to provide a satisfactory explanation. The giving of the vitamin in increasing doses by mouth and only later by the intramuscular or, in exceptional cases, by the intravenous route, is recommended.—D. Harvey.

WINKEL, W. E. F. Irreparable changes of the spinal cord after pellagra. *Doc. Med. geogr. trop.*, 1954, 6, 296-302.

A patient who had been a prisoner of war in the Dutch East Indies was admitted to the university hospital in Leyden in 1946. He was reputed to have had typical pellagra and other "camp anomalies". On admission to hospital he complained of stiff and insensitive hands and legs, with tingling of hands and feet, unmanageable arms and legs, loss of muscle power and a swollen feeling in the lips, gums and tongue. Six months later he died of bronchopneumonia and endocarditis. There were degenerative changes in the spinal cord which are described in detail.—E. M. Hume.

4120

ALTSCHUL, R., HOFFER, A. and STEPHEN, J. D. Influence of nicotinic acid on serum cholesterol in man. *Arch. Biochem. Biophys.*, 1955, 54, 558-559. [Lab. Gerontol., Univ. Saskatchewan, Saskatoon.]

In trials to find out whether direct stimulation of respiratory enzyme activity would influence serum cholesterol, nicotinic acid, which is a component of the respiratory coenzyme system, was given to rabbits by mouth 3 times daily in doses of from 0.18 to 0.045 g.; it was usually followed by a decrease in serum cholesterol.

In 11 healthy medical students, 4 g. nicotinic acid given by mouth in 4 spaced doses of 1 g. during 24 hr. was followed by an average decrease of 8.4 per cent. in serum cholesterol of which the previous average value had been 204 mg. per 100 ml. In a series of 57 patients who received a single dose of 1 g. nicotinic acid, a decrease in serum cholesterol occurred also, the amount of the decrease depending on the initial value. If the total of 68 subjects was divided into 2 groups with serum cholesterol values under and over 250 mg. per 100 ml., the average percentage decrease in the first group was 6.4, and in the second 21.7.

Since all the students reacted to the nicotinic acid with flushing and burning skin sensations, it is considered possible that this stress reaction may have been a cause contributing to the decrease in serum cholesterol.

In parallel tests with 20 healthy medical students who received nicotinamide there was no effect on serum cholesterol.

The studies just described are connected with attempts to prevent experimental arteriosclerosis in rabbits and to reduce serum cholesterol in patients with degenerative vascular disease.

4121

BIEHL, J. P. and VILTER, R. W. Effects of isoniazid on pyridoxine metabolism. *J. Amer. Med. Assoc.*, 1954, 156, 1549-1552. [Dept. Int. Med., Coll. Med., Univ. Cincinnati, Ohio.]

Of 74 previously untreated patients treated with the drug isoniazid in doses from 6 to 24 mg. per kg. bodyweight some developed symptoms of neuritis in from 5 weeks to 6 months. The incidence was greater, 14 of 32, in patients receiving the highest dose. The excretion of vitamin B₆ increased up to 4 times normal in some after administration of isoniazid and fell on its withdrawal. When vitamin B₆ was given with isoniazid neuritis did not develop. The isonicotinyl hydrazone of pyridoxal was formed *in vitro* by the coupling of pyridoxal and isoniazid. The hypothesis that this compound is excreted is advanced to explain the depletion of vitamin B₆ by isoniazid.—A. Hepburn.

4122

KERPOLA, W. and PÄTÄLÄ, J. Pyridinenucleotides (coenzyme I and II) of blood in normal subjects and in various diseases, especially tuberculosis. *Ann. Med. exp. Biol. Fenn.*, 1954, 32, Suppl. 7, pp. 30. [I. Med. Dept., Univ. Helsinki.]

Pyridine nucleotides were estimated by the fluorimetric method of Levitas *et al.* (Abst. 433, Vol. 17) in blood from 41 healthy subjects and 253 patients with various diseases. The content of total pyridine nucleotides in $\mu\text{g. per ml.}$ was 28.1 ± 0.69 in normal whole blood and 67.1 ± 1.49 in normal red cells; in 92 patients with tuberculosis of different degrees of severity the corresponding values were 24.0 ± 0.34 and 54.0 ± 0.60 . Low values for pyridine nucleotides were found also in the blood of schizophrenic patients and those with asthenia associated with neurocirculatory disturbances. In digestive, rheumatic and circulatory disorders the pyridine nucleotides of the blood were within normal limits. In some endocrine disorders and some patients with leucæmia the values were raised. The relation of the pyridine nucleotide content of the blood to general metabolic disturbance is discussed.—A. M. Copping.

4123

DEB, A. K. Modified insulin and vitamin B-complex treatment in some common mental ailments. *Calcutta Med. J.*, 1954, 51, 375-377. [Lumbini Park, Calcutta.]

The cases of 5 patients with mental disorders, schizophrenia, hysteria or anxiety states are discussed; all of them showed improvement after combined treatment with insulin and injections of vitamin B complex, and with powder of the plant *Rauwolfia serpentina* and light psychotherapy. J. S. Thomson.

4124

ŠPAČEK, M. Physiological investigations on the excretion of kynurenine in humans. *Canad. J. Biochem. Physiol.*, 1955, **33**, 14-20. [Dept. Health and Welfare, Charlottetown, Prince Edward Island.]

Kynurenine was estimated by a method which has previously been described (Abst. 1620, Vol. 25) in urine from healthy adults and from inmates of an institution for old people. In specimens obtained at different times of the day or night, and in total urine for different days from the same subjects, variations of from 13 to 16 per cent. were found. Subjects with high values for kynurenine excretion showed decreased values when tryptophan was eliminated from the diet by institution of a vegetarian regime without milk, cheese or eggs. Doses of 2 or 3 g. tryptophan caused a rise in kynurenine excretion, but smaller doses had little or no effect. Administration of nicotinamide caused a decrease in kynurenine excretion, but pyridoxine had no consistent effect.

There appeared to be a relation between age and extent of kynurenine excretion. Young adults excreted on the average 0.1 mg. per 100 ml. urine, older persons of average age 47 years 0.21 mg. per 100 ml., and averages were even higher in subjects over 70 years. No marked difference was found between male and female subjects.

A. M. Copping.

4125

GRÜBER, H. L. E. Mitteilung über die Wirksamkeit von Vitamin B₆ bei Alkoholrausch. [Activity of vitamin B₆ in alcoholic intoxication.] *Münch. med. Wochenschr.*, 1954, **96**, 1445. [Pathol. Inst., Jung - Stilling - Krankenhaus, Siegen i.W.]

In mice the toxic effect of the DL50 dose of alcohol was appreciably decreased when pyridoxine hydrochloride was injected also.

Human subjects were set to make a simple calculation before and after taking the equivalent of from 1 to 2 ml. absolute alcohol per kg. body-weight, and again, a little later, after injection of 0.05 g. pyridoxine hydrochloride. Neither subjective nor objective benefit was obtained from giving vitamin B₆ in 9 subjects. The findings did not support the theory that vitamin B₆ might be used to counteract the effects of alcohol in man.

A. M. Copping.

4126

CHOWDHURY, S. R., RAJAGOPAL, K. and CHAKRABORTY, A. N. Influence of pyridoxine on fat metabolism in phrynoderma. *Indian Med. Gaz.*, 1954, **89**, 283-287. [Sect. Biochem. Nutr., All India Inst. Hyg. Pub. Health, Calcutta.]

The possible role of vitamin B₆ in phrynoderma is reviewed with reference to fat metabolism. In a study of 24 patients with phrynoderma, 4 received 10 mg. pyridoxine daily by mouth, 4 had 50 mg. pyridoxine twice weekly by injection, and the others had raw linseed oil alone or with pyridoxine by mouth or by injection. Pyridoxine alone had no effect on the skin but injection of pyridoxine while linseed oil was being given enhanced the curative effect of the oil. The cholesterol and fatty acid contents of the blood serum were estimated. There was a significant increase in the iodine number of the fatty acids and in the blood cholesterol of patients given linseed oil with pyridoxine by injection.—A. M. Copping.

4127

ZUMOFF, B. Failure of folic acid to affect uric acid metabolism in a case of gout. *Metabolism*, 1955, **4**, 80-81. [Lab. Med. Serv., Veterans Admin. Hosp., Brooklyn, N.Y.]

In view of the relation between folic acid and xanthine oxidase in chicks, and the beneficial effect of folic acid on serum uric acid in a case of sprue (Abst. 1106, Vol. 24), an attempt was made to treat a patient with gout by intramuscular and oral doses of folic acid. No benefit was obtained.

A. M. Copping.

COLSKY, J., GREENSPAN, E. M. and WARREN, T. N. Hepatic fibrosis in children with acute leukemia after therapy with folic acid antagonists. *Arch. Pathol.*, 1955, **59**, 198-206. [Clin. Res. Unit, Nat. Cancer Inst., U.S. Pub. Health Serv., Dept. Health, Baltimore, Md.]

Detailed clinical reports are given of the results in 5 children of treating acute leucemia with A-methopterin or aminopterin. Doses of up to 10 mg. A-methopterin or 2 mg. aminopterin were given daily for several months; remission of the disease occurred but could not be maintained even with continued treatment. Clinical and laboratory signs of hepatic fibrosis appeared in all the subjects and at autopsy there was extensive fibrosis. The problem of the effect on the liver of folic acid antagonists is discussed.—A. M. Copping.

4129

WATSON, R. J., LICHTMAN, H. C., MESSITE, J., ELLISON, R. R., CONRAD, H. and GINSBERG, V. Clinical studies with the citrovorum factor

in megaloblastic anemia. *Amer. J. Med.*, 1954, 17, 17-28. [Dept. Med., Coll. Med., State Univ. New York.]

A woman with pernicious anaemia in relapse given 5 mg. citrovorum factor by mouth daily had normal blood values within 2 months, but 2 months later she developed for the first time neurological signs which responded to vitamin B₁₂ given parenterally.

Five patients with megaloblastic anaemia of nutritional origin gave a haematological response to citrovorum factor; 4 of them had failed to respond to vitamin B₁₂. Two were thought to have a deficiency of both vitamin B₁₂ and citrovorum factor.

It is concluded that citrovorum factor is contraindicated in pernicious anaemia but is equal in value to folic acid for treatment of nutritional megaloblastic anaemia.—D. Duncan.

4130

SCHWARTZ, S. O., FRIEDMAN, I. A. and GANT, H. L. Long-term evaluation of vitamin B₁₂ in treatment of pernicious anemia. 1. Incidental report on use of combined oral therapy with vitamin B₁₂ and folic acid. *J. Amer. Med. Assoc.*, 1955, 157, 229-231. [Lab. Haematol., Cook County Hosp., Ill.]

Clinical, haematological and neurological evaluation of treatment extended to over 4 years in 34 of 63 patients given injections of liver extract and in 32 of 51 given injections of vitamin B₁₂. The amounts given were generally 30 U.S.P.U. liver extract or 30 µg. vitamin B₁₂ every 4 weeks, more to patients with neurological symptoms. In the group given liver extract 3 patients had slight recurrence of paraesthesiae, and in the group given vitamin B₁₂ there were 4 neurological relapses, which were reversed by higher doses of vitamin B₁₂ or by adequate liver therapy. In a group of 36 patients given orally 25 µg. vitamin B₁₂ and 1.67 mg. folic acid daily, the incidence of neurological relapse was high, and this form of treatment is not recommended.—F. C. Aitken.

MUELLER, J. F. and WILL, J. J. Interrelationship of folic acid, vitamin B₁₂ and ascorbic acid in patients with megaloblastic anemia. *Amer. J. Clin. Nutr.*, 1955, 3, 30-44. [Dept. Int. Med., Coll. Med., Univ. Cincinnati, Ohio.]

Studies during the past 8 years are discussed in relation to the effect of folic acid and vitamin B₁₂ on different types of megaloblastic anaemia in man. The probable role of ascorbic acid in human anaemia is reviewed. The present knowledge of nucleoprotein metabolism is considered in connection with pernicious anaemia and other macrocytic anaemias. A schematic representation of the present knowledge of metabolic interrelationships of the three vitamins is suggested.

GILLIESPY, R. O. The treatment of pernicious anaemia with vitamin B₁₂ insufflation. *Practitioner*, 1955, 174, 177-179. [Haematol. Clin., Dudley Road Hosp., Birmingham.]

Twenty-six patients with pernicious anaemia satisfactorily controlled with liver extract or cyanocobalamin given parenterally suffered no setback over a period of from 12 to 18 months when treated by cyanocobalamin insufflation, the vitamin being taken directly from the back of the hand in doses of 100 µg. a week. New cases of pernicious anaemia in relapse, 19 in all, responded satisfactorily to cyanocobalamin taken by insufflation, 100 µg. daily for 14 days, and then 100 µg. weekly.

The method of treatment is not recommended in cases of chronic nasal catarrh or for patients incapable of carrying out, effectively, the simple instructions.—F. C. Aitken.

KREBS, A. Die orale Therapie der perniziösen Anämie mit Vitamin B₁₂ und Magenschleimhautextrakt. [Oral treatment of pernicious anaemia with vitamin B₁₂ and an extract of gastric mucosa.] *Münch. med. Wochenschr.*, 1954, 96, 1451-1453. [Innere Abt., Städt. Krankenhaus, Siegburg.]

Reports are given of the response of 8 patients with untreated pernicious anaemia to capsules containing 2.5 or 5.0 µg. crystalline vitamin B₁₂ and a dried preparation of pig's gastric mucosa equivalent to at least 3 units of apoerythrin. The reticulocyte response to from 3 to 5 of the capsules daily given by mouth was very little slower than to injected vitamin B₁₂, and the blood picture returned to normal in from 9 to 13 days. It was maintained with a dose of one capsule daily.

A. Copping.

4138

HÖRLIN, W. Die perorale Behandlung der perniziösen Anämie mit konzentriertem Intrinsic Factor und Vitamin B₁₂. [Oral treatment of pernicious anaemia with concentrated intrinsic factor and vitamin B₁₂.] *Münch. med. Wochenschr.*, 1954, 96, 1513-1516. [Med. Klin., Stadtkrankenhaus, Hof a.d. Saale.]

Tablets containing 10 µg. vitamin B₁₂ and 0.5 U.S.P. unit of intrinsic factor were given to 17 patients with pernicious anaemia. A reticulocyte response was obtained in most patients after 15 tablets had been given in 5 days, though a longer period of treatment was needed for some patients. When the blood picture was restored and the other signs and symptoms had disappeared, a satisfactory maintenance dose was 3 tablets a week.

4139

WILLIAMS, W. L., ELLENBOGEN, L. and ESPOSITO, R. G. Preparation of highly purified intrinsic factor. *Proc. Soc. Exp. Biol. Med.*, 1954, 87, 400-405. [Nutrit. Physiol. Sect., American Cyanamid Co., Res. Div., Lederle Labs., Pearl River, N.Y.]

Intrinsic factor prepared from pig's stomach dried and defatted at low temperature was purified by fractionation with ammonium sulphate, followed by proteolytic digestion and alcohol fractionation. The final fraction was further purified by ultrafiltration and the preparation was active for pernicious anaemia patients in doses of 1 or 2 mg. with vitamin B₁₂. Analysis by electrophoresis and ultracentrifuging indicated that the active component had a molecular weight of about 5000, contained hexosamine and was probably a mucopolypeptide. The hexosamine portion of the molecule was shown by a differential colorimetric method to contain glucosamine and presumably chondrosamine hydrochloride.—A. M. Copping.

DI RAIMONDO, F., ANGARANO, D. and MANNINO, N. Aspetti e limiti della disvitaminosi da antibiotici: osservazioni e ricerche in soggetti sani. [Some aspects and limits of vitamin deficiency induced by antibiotics: observations and studies on healthy subjects.]

DI RAIMONDO, F., MANNINO, N., ANGARANO, D. and SCHIRALDI, O. Prevenzione della disvitaminosi da antibiotici: ricerche sperimentali in soggetti sani e osservazioni cliniche in malati. [Prevention of vitamin deficiency induced by antibiotics: experimental studies on healthy subjects and clinical observations on patients.] *Internat. Ztschr. Vitaminforsch.*, 1955, 25, 407-426; 427-433. [Ist. Clin. Med., Univ. Bari.] English summary.

Thirteen healthy subjects aged from 20 to 35 years were maintained on a constant diet of convalescent-hospital type. In the 24-hr. urine, vitamin B₁, riboflavin and nicotinic acid were estimated chemically, and vitamin B₆, vitamin B₁₂ and folic acid microbiologically. All the subjects except one were given chloramphenicol daily for 7 days. [The amount is sometimes stated as 2.5 g. daily and sometimes as 2.5 mg.] The thirteenth was given terramycin and aureomycin. Test intramuscular injections of a single B vitamin in moderate or large doses were given before the course of antibiotic and again at the end of it. [Detailed protocols are set out for every subject but there is no table summarising results.] Under the influence of the antibiotic the amount of all the 6 vitamins in the urine fell steadily, the fall being greatest with nicotinic acid, folic acid and vitamin B₁₂. The retention of more of the test dose after antibiotic treatment than before was taken as evidence of the state of deficiency induced by the antibiotic.

B vitamins in the urine of 6 healthy subjects were estimated as in the preceding experiment before, and daily during, treatment with 10 tablets of a preparation containing 250 mg. chloramphenicol and physiological doses of vitamin C, nucleic acid and 8 B vitamins. The fall in excretion of B vitamins in the urine caused by chloramphenicol was completely prevented and sometimes reversed. The same preparation was given to 11 patients with infectious diseases requiring antibiotic treatment. The inclusion of the vitamins had no undesirable effect on the action of the antibiotic, and prevented signs of deficiency, such as occasionally occur.—E. M. Hume.

BAKER, S. J. and MOLLIN, D. L. The relationship between intrinsic factor and the intestinal absorption of vitamin B₁₂. *Brit. J. Haematol.*,

1955, 1, 46-51. [Dept. Pathol. (Haematol.), Postgrad. Med. Sch., London.]

The absorption of small doses of vitamin B₁₂ labelled with ⁵⁸Co and given with varying amounts of intrinsic factor from pig's stomach was studied in patients with pernicious anaemia in remission after treatment with vitamin B₁₂. The amount of radio-activity in the faeces showed that, over a limited range, there was a stoichiometric relationship between the amount of vitamin B₁₂ absorbed and the amount of intrinsic factor administered. Beyond that range increase in the amount of intrinsic factor did not increase the absorption of vitamin B₁₂. The ability to absorb vitamin B₁₂ showed individual variation in the 6 patients studied. If large amounts of unlabelled vitamin B₁₂ were injected some hours before or shortly after the oral test dose the intestinal absorption of the radio-active vitamin B₁₂ decreased.

SCHILLING, R. F. The absorption and utilization of vitamin B₁₂. *Amer. J. Clin. Nutr.*, 1955, 3, 45-49 (with discussion 49-51). [Dept. Med., Med. Sch., Univ. Wisconsin, Madison.]

The importance of intrinsic factor in absorption of vitamin B₁₂ from the intestine is discussed. Gastric mucosa is apparently the only source of intrinsic factor in man; in its presence the requirement of vitamin B₁₂ is about 1 µg. daily. The very slow breakdown of absorbed vitamin B₁₂ is discussed with reference to the length of the remissions in pernicious anaemia induced by treatment with vitamin B₁₂, and also to the persistence of radio-activity in the liver for long periods after administration of radio-active vitamin B₁₂.

GLASS, G. B. J., BOYD, L. J., STEPHANSON, L. and JONES, E. L. Metabolic interrelations between intrinsic factor and vit. B₁₂. 3. B₁₂ absorption at varied intrinsic factor doses.

GLASS, G. B. J. and JONES, E. L. 4. Relative thermostability of some intrinsic factor preparations. *Proc. Soc. Exp. Biol. Med.*, 1955, 88, 1-5; 69-73. [Dept. Med., New York Med. Coll.]

3. The uptake of radio-active vitamin B₁₂, given by mouth mixed with intrinsic factor from pig's stomach or from human gastric juice, was measured from counts of radio-activity over the liver area in 6 patients with pernicious anaemia, one patient after total gastrectomy and one normal subject. With a constant dose of vitamin B₁₂, increasing amounts of intrinsic factor increased the amount of vitamin absorbed up to a point beyond which further increase in intrinsic factor did not raise absorption and in some in-

stances even decreased it. This latter effect might have been due to excess intrinsic factor binding vitamin B₁₂ and preventing its absorption.

4. The activity of intrinsic factor preparations from heated and unheated human gastric juice and from pig's stomach was measured by giving the materials with radio-active vitamin B₁₂ and making surface scintillation measurements of the amount of vitamin absorbed. It was confirmed that human intrinsic factor was thermolabile and that it was destroyed or inactivated by boiling at pH from 1.2 to 1.4 for 30 min. Preparations from pig's stomach were destroyed by boiling at pH 1.2, but not at pH 6.0. The problem of the relative stability of some preparations at neutrality is discussed.—A. M. Copping.

FRANZ, W. and PENDL, I. Über den Einfluss der Bakterienbesiedlung des Magens auf die perorale Vitamin B₁₂-Resorption bei perniziöser Anämie. [Influence of the bacterial flora of the stomach on the absorption of vitamin B₁₂ given orally in pernicious anaemia.] *Klin. Wochenschr.*, 1954, 32, 1092-1096. [2. Med. Klin., Univ. Frankfurt a.M.]

In the gastric juice of treated and untreated patients with pernicious anaemia, *Bacterium coli* was present in all except 3 whose anaemia was severe and who had never been treated, but who, notwithstanding, had relatively high values for the number of reticulocytes in the circulating blood. The evidence that absence of *Bact. coli* from the gastric juice can cause a spontaneous remission of pernicious anaemia is discussed. The gastric juice of the 3 patients contained no bound vitamin B₁₂ and was incapable of binding it *in vitro*. Treatment of 2 of the patients with small daily doses, 5, 10 and 30 µg. of vitamin B₁₂ given orally was successful after 98 days in one but failed in the other with appearance of paracoli bacteria in the gastric juice.

The authors suggest that vitamin B₁₂ given orally can be absorbed by patients with pernicious anaemia if it is not first destroyed by *Bact. coli*, and that the binding of vitamin B₁₂ protects it from the micro-organisms.—E. M. Hume.

GLASS, G. B. J., BOYD, L. J. and GELIN, G. A. Surface scintillation measurements in humans of the uptake of parenterally administered radioactive vitamin B₁₂. *Blood, J. Hematol.*, 1955, 10, 95-114. [Dept. Med., New York Med. Coll.]

A procedure is described for making surface measurements of radio-activity in underlying organs of human subjects who have received injections of vitamin B₁₂ containing ⁶⁰Co. In two

N.A. and R., July 1955

young patients with no anaemia, and in a man of 55, 18 months after total gastrectomy, the radio-activity disappeared rapidly from the site of injection and within 4 hr. rose to its highest value in areas over the kidneys, spleen and iliac crest. The peak value in muscles occurred somewhat later, and in the liver after 5 or 6 days. Radio-activity decreased very slowly and after 3 months was from one-half to one-quarter of the peak values. The decline was slowest in the liver and iliac crest areas.

In a patient with pernicious anaemia in partial remission the uptake of radio-active vitamin B₁₂ was greater than in the subjects just described, and the decline in radio-activity was more rapid. In this patient and in one with sprue a high percentage of the peak value still persisted over the liver after 5 months. The long storage of vitamin B₁₂ in the liver shown by these observations may explain the long remissions found when pernicious anaemia is treated by injection of vitamin B₁₂ or liver extracts.—A. M. Copping.

GROSSOWICZ, N., ARONOVITCH, J. and RACHMILEWITZ, M. Determination of vitamin B₁₂ in human serum by a mutant of *Escherichia coli*. *Proc. Soc. Exp. Biol. Med.*, 1954, **87**, 513-514. [Dept. Bacteriol., Hadassah Med. Sch., Hebrew Univ., Jerusalem.]

Vitamin B₁₂ was estimated with *Bacterium coli* 113/3 in a medium containing a methionine-free hydrolysate of casein. Satisfactory results could be obtained for blood serum in from 40 to 48 hr. In 30 normal subjects the vitamin B₁₂ content of the serum, in $\mu\mu\text{g}$. per ml., ranged from 200 to 1000. Patients with untreated pernicious anaemia showed values of from 50 to 150 and after treatment of from 500 to 1050.—A. M. Copping.

4149

LEAR, A. A., HARRIS, J. W., CASTLE, W. B. and FLEMING, E. M. The serum vitamin B₁₂ concentration in pernicious anemia. *J. Lab.*

Vol. 25, No. 3

Clin. Med., 1954, **44**, 715-722. [Thorndike Mem. Lab., Boston City Hosp., Mass.]

The vitamin B₁₂ content of human serum was measured microbiologically with *Englena gracilis*. The mean values, in $\mu\mu\text{g}$. per ml., were 532 for 20 normal subjects, 39 in 33 patients with pernicious anaemia in relapse, 525 in 22 cases of pernicious anaemia in remission, 439 in 14 patients with neurological signs but no anaemia, 307 in 12 patients with macrocytic anaemia which responded to folic acid, and 714 in 29 patients with cirrhosis of the liver. In patients taking sulphonamides the presence of derivatives in the serum inhibited the growth of *Englena* but the inhibition could be overcome by adding *p*-aminobenzoic acid to the medium. Capacity to bind vitamin B₁₂ into complexes from which it was not available to *Englena* was about the same in patients with pernicious anaemia as in normal subjects.—A. M. Copping.

4150

PATRICK, S. J. Some observations on the metabolism of vitamin B₁₂ by Jamaican children. *J. Nutrition*, 1955, **55**, 129-135. [Dept. Physiol., Univ. Coll. West Indies, Jamaica.]

Two groups of 19 children, comparable in age, sex and economic status, were chosen from a Jamaican village. One group received vitamin B₁₂ by mouth for 9 months and the other group had a dummy. The children having vitamin B₁₂ had significantly higher values for vitamin B₁₂ in the blood plasma. Excretion of vitamin B₁₂ in the urine was studied in 2 children who had repeated injections of the vitamin and, though the value in the plasma rose, the percentage of the dose excreted did not increase significantly. The urinary excretion of vitamin B₁₂ was not very different in normal children after a test dose and in children showing retarded growth after a test dose or a dietary supplement of vitamin B₁₂.

4151

KARLIN, R. Variations du taux de vitamine B₁₂ dans le lait de femme au cours de la lactation. [Variations in the vitamin B₁₂ content of human milk during lactation.] *C.R. Soc. Biol.*, 1954, **148**, 1419-1422. [Inst. Pasteur, Lyons.]

Vitamin B₁₂ was estimated with *Lactobacillus leichmannii* in human colostrum and milk at different stages of lactation. The highest values, ranging from 1.35 to 7.90 $\mu\mu\text{g}$. vitamin B₁₂ per ml., were found in colostrum. As lactation progressed there was a decrease up to the third month when a consistently low average value of 0.26 $\mu\mu\text{g}$. per ml. was found. After the third month little variation occurred. It is noted that in cow's milk variations in the vitamin B₁₂ content may be considerable in the later stages of lactation.

A. M. Copping.

HOUGS, W. and SKOUBY, A. P. **The anti-anaemic action of extracts from placenta.** *Acta med. scand.*, 1954, 150, 453-458. [Res. Lab., Gea, Copenhagen.]

Placentas and other organs were obtained from cows and rabbits killed towards the end of pregnancy, and human placentas at delivery. Extracts were prepared with vitamin-B₁₂-like activity.

The greatest activity shown in microbiological tests with animal tissues was in kidney, spleen, liver and placenta, but for any one tissue there was wide variation. In human placenta the activity corresponded to from 5 to 40 μg . vitamin B₁₂ per g. wet tissue.

Placenta extract was given parenterally to 9 patients with Addisonian anaemia in relapse, and was effective in producing and maintaining full remission, including recovery from nerve symptoms in 5 of the patients. In one patient with atypical megaloblastic anaemia not influenced by liver extract or vitamin B₁₂, a submaximum response to placenta extract was followed by full response to folic acid with gastric mucosal extract, but in another patient resistant to vitamin B₁₂, folic acid and liver extract, there was no response to placenta extract.—D. Duncan.

4153

PITNEY, W. R., BEARD, M. F. and VAN LOON, E. J. **The vitamin B₁₂ content of electrophoretic fractions of liver homogenates.** *J. Biol. Chem.*, 1955, 212, 117-123. [Sect. Haematol., Dept. Med., Sch. Med., Univ. Louisville, Ky.]

Euglena gracilis was used to measure the vitamin B₁₂ content of livers from 12 healthy subjects who had died suddenly. The values in μg . per g. wet tissue ranged from 0.11 to 0.47, mean 0.28. Vitamin B₁₂ appeared to be present in liver as a loosely bound protein complex which was available to *E. gracilis*. It differed in this respect from vitamin B₁₂ in serum, which was not available to *E. gracilis* without preliminary heat treatment. Electrophoretic fractionation of liver homogenates showed that the migration of vitamin B₁₂ corresponded to the movement of serum β -globulin on a control strip. Estimation of the vitamin B₁₂ in the different fractions accounted for the whole of the vitamin B₁₂ activity.—A. M. Copping.

4154

BAOCHER, K. R. **Vitamin B₁₂ zur Behandlung des Alkoholdeliriums.** [Treatment of delirium tremens with vitamin B₁₂.] *Deutsch. med. Wochenschr.*, 1954, 79, 1901-1903. [Chirurg. Abt., Städt. Krankenhaus "Hetzelstift", Neustadt a. d. Weinstrasse.]

All but one of 7 patients, regular drinkers of 3 or more litres of wine daily, who developed de-

lirium tremens after accident or operation, were treated successfully with one or more intramuscular injections of 1000 μg . vitamin B₁₂ (Berubi-1000, Dr. Wachter und Gross GmbH, Bad Ems). The prophylactic use of smaller amounts, from 48 to 333 μg ., in patients thought to be in danger of developing delirium tremens after accident or operation is proposed. The trial was suggested by the results of Lereboullet and Pluvinaige (*J. Amer. Med. Assoc.*, 1952, 148, 667) and Menof (Abst. 4092, Vol. 21) in patients with alcoholic polyneuritis.—W. M. Deans.

CAMPBELL, R. E. and PRUITT, F. W. **The effect of vitamin B₁₂ and folic acid in the treatment of viral hepatitis.** *Amer. J. Med. Sci.*, 1955, 229, 8-15. [Med. Serv., U.S. Army Hosp., Kyoto.]

Two groups of 44 patients with severe viral hepatitis were matched for race, age, duration of illness and intensity of jaundice. Both groups received the usual high-protein, high-carbohydrate, moderate-fat diet, and one group received an intramuscular injection of 30 μg . vitamin B₁₂ every other day, and 15 mg. folic acid daily by mouth, for the first 10 days in hospital. The addition of vitamin B₁₂ and folic acid caused more rapid recovery of appetite, and return of normal values for serum bilirubin and bromosulphalein retention. The mean duration of illness was 47.5 days for the group given vitamin B₁₂ and folic acid, and 57.2 days for the others. The effect of the vitamins was most marked in patients with high total serum bilirubin before treatment began.

N.A. and R., July 1955

The theoretical reasons for the value of vitamin B₁₂ and folic acid in repairing liver damage are discussed.—A. M. Copping.

SINGH, A. Infantile scurvy in the Punjab. *Indian Med. Gaz.*, 1954, **89**, 288-289. [Rajendra Hosp., Patiala.]

Scurvy is considered to be the commonest deficiency disease among children in the Punjab. During the last 5 years 16 cases of infantile scurvy and 4 of rickets have been encountered. The children with scurvy were usually between 1 and 2 years old; their mothers were poor and ill fed, and the babies were weaned on to cow's milk when 4 or 5 months old. None of them had had any fruit juice. Three typical case histories are given. Scurvy is said to be rare in adults.

FISHER, K. H. and DODDS, M. L. Variability in the measure of total ascorbic acid utilization by the human. *J. Nutrition*, 1954, **54**, 389-396. [Coll. Home Econ., Pennsylvania State Univ., State College.]

In healthy young women the effect of both high and low intakes of total ascorbic acid was still evident in the blood plasma at least 23 days after the intake of ascorbic acid was changed. Excretion of total ascorbic acid in the urine was adjusted more rapidly. A daily supplement of 50 or 125 mg. synthetic ascorbic acid was given to women having a basal diet containing 25 mg. total ascorbic acid. There was no significant difference in the plasma or urinary total ascorbic acid values whether the daily dose was given at one meal or divided at 2 meals.

An adjustment period of from 10 to 17 days preceded a 10-day test in 2 small groups of women, one given 60 and the other 75 mg. ascorbic acid daily. Blood plasma values and the urinary excretion of total ascorbic acid in the 24 hr. were significantly different in the 2 groups.

POTGIETER, M., MORSE, E. H. and WALKER, G. R. Ascorbic acid utilization by women. Response of serum level and night urinary excretion to increasing levels of intake. *J. Nutrition*, 1955, **55**, 217-224. [Sch. Home Econ., Univ. Connecticut, Storrs.]

Twenty mentally retarded women aged from 27 to 63 years, in good physical health, were studied. After 2 months of a diet restricted by the omission of citrus fruits and tomatoes to provide 45 mg. ascorbic acid daily, the subjects were divided into 2 groups, of which one received daily in addition 25 mg. ascorbic acid during the third month of study, 50 mg. during the fourth month and 100 mg. during the fifth month. The other group meanwhile received the same diet without supplement. Ascorbic acid was estimated in venous blood at the beginning of the study, after one and two months on the restricted diet, and at the end of each subsequent month, and also in 8-hr. night urine samples twice near the end of each period when supplements were given.

The average serum ascorbic acid value for the 20 subjects fell from 0.97 to 0.42 mg. per 100 ml. during the 2 months of restricted intake. The maximum average value of 1.49 mg. per 100 ml. was reached after a month of the 50-mg. supplement. The average value for the untreated group dropped to 0.13 at the end of the 5 months of restricted diet. The average value for total ascorbic acid in the 8-hr. night urine increased very slightly with the supplements of 25 and 50 mg. but did not rise above 5 mg. until the end of the month with the 100-mg. supplement when it increased to 30 mg. The amount excreted by the untreated group remained at about 2 mg. throughout the study.—G. F. Garton.

4164

OGLIVIE, G. F. and PETT, L. B. A long term study on ascorbic acid supplementation. *Canad. Serv. Med. J.*, 1954, 10, 191-197. [Nutrit. Div., Dept. Nat. Health and Welfare, Ottawa.]

In the school selected for study the daily intake of ascorbic acid was about 50 mg. per head; the incidence of poor oral hygiene with associated gingivitis was high. The children were divided into 2 groups which received tablets with 100 mg. ascorbic acid or dummies daily for 4 years. Of the total number of 165 children, 89 completed the study.

The values for serum ascorbic acid were significantly higher in the group given ascorbic acid, but there was no significant difference in the Hb values or incidence of gingivitis. Red and swollen gums, characteristic of gingivitis but not of scurvy, occurred in about 21 per cent. of the children, whether they received the supplement of ascorbic acid or not.—F. C. Aitken.

BAKER, A. Z. and WINCKLER, I. Vitamin C for the prevention of winter absence in industry. *Med. Officer*, 1955, 93, 31-32. [Dept. Med. Res., Vitamins, Ltd., London.]

The effect of a daily supplement of 100 mg. ascorbic acid on the incidence of short absences from work was studied in an industrial organisation during 3 successive winters. The groups given and not given the supplement totalled for the 3 years about 600 persons. The results suggested that a winter supplement of 100 mg. ascorbic acid daily helped to reduce absences of short duration.

PASSARO, G. Protrombina, fattore V e VII nel neonato. [Prothrombin and factors V and VII in the newborn.] *Arch. ital. Pediat. Puericolt.*, 1955, 17, 59-90. [Ist. Clin. Pediat.

Univ. Rome.] French, English and German summaries.

Factor V was estimated by the method of Quick and Stefanini (*J. Lab. Clin. Med.*, 1948, 33, 819), and prothrombin and Factor VII by methods of Koller and his colleagues, in the blood of 31 healthy newborn infants on the first or second day of life, and of 10 between the first 2 days and 2 weeks. Estimation of the prothrombin time of Quick gave varying results considered unreliable. The prothrombin content estimated by the method of Koller was low even in the second week of life. The values for Factor V were normal. The values for Factor VII were very low, the mean being only a quarter of that in the adult, and they remained so into the second week of life.—E. M. Hume.

STÜRUP, H. Effects of intravenously injected vitamin K₁ and water-soluble vitamin K (menadione sodium bisulphite) on hypoprothrombinaemia during anticoagulation treatment. *Acta med. scand.*, 1954, 150, 437-442. [Med. Dept. B., Frederiksberg Hosp., Copenhagen.]

Twenty patients under treatment with dicoumarol were given, by intravenous injection, 50 mg. menadione sodium bisulphite or from 10 to 40 mg. vitamin K₁. Prothrombin activity was measured before, at the time of, and 1, 2, 6 12 and 24 hr. after injection. The effect of vitamin K₁ was both greater and quicker than that of menadione sodium bisulphite and, in patients in whom activity was low, the amount of vitamin K₁ given would produce in from 2 to 6 hr. the same therapeutic effect as 50 mg. of the water-soluble product in from 12 to 24 hr.

GAMBLE, J. R., DENNIS, E. W., COON, W. W., HODGSON, P., WILLIS, P. W. (III), MACRIS, J. A. and DUFF, I. F. Clinical comparison of vitamin K₁ and water-soluble vitamin K. *Arch. Int. Med.*, 1955, 95, 52-58. [Dept. Int. Med., Univ. Michigan Hosp., Ann Arbor.]

Patients with low blood prothrombin caused by anticoagulant drugs were treated more effectively by vitamin K₁ than by the water-soluble vitamin K preparation menadione sodium bisulphite, which had an inconstant and unreliable effect. In

N.A. and R., July 1955

many cases from 1 to 5 mg. vitamin K₁ by mouth gave a satisfactory response in 4 hr. and permitted the early resumption of anticoagulant therapy. In patients with absorption difficulties the 2 substances were about equally effective. Vitamin K₁ seemed the more effective in patients with severe liver disease.—A. Hepburn.

GUSTAFSSON, B. E., QUENSEL, C. E., LANKE, L. S., LUNQVIST, C., GRAHNEN, H., BONOW, B. E. and KRASSE, B. The Vipeholm dental caries study. The effect of different levels of carbohydrate intake on caries activity in 436 individuals observed for five years. *Acta odontol. scand.*, 1954, 11, 232-364. [Dent. Res. Stat., Royal Med. Board, Vipeholm Hosp., Lund.]

Vol. 25, No. 3

The study began in March 1945 and the present report is a revised edition of one in Swedish in *Sv. Tandl.-Tidskr.*, 1952, 45, Suppl.

There were 4 stages, a preparatory period, 1945, a vitamin study period, 1946 to 1947, when vitamins A, C or D or a combination of these were tested, and two carbohydrate study periods, 1947 to 1949 and 1949 to 1951, when the carbohydrate intake was increased and sources which differed in their degree of stickiness were used. In these latter periods the groups were: a control group to which the basal diet without added carbohydrate was given, a sucrose group to which this non-sticky form was given at meals, a bread group given carbohydrate at meals in this form with its tendency to be retained on the surfaces of the teeth and 4 other groups given sugar, between meals, as chocolate, caramel, or toffees at 2 levels.

The subjects were mentally deficient patients in an institution near Lund; their average age was about 32 years and they were under continuous observation. Their mental condition, age, low standard of oral hygiene and the low incidence of caries found among them in the preliminary study made their susceptibility difficult to judge; the findings, it is thought, would probably have been more pronounced with a population of ordinary and younger subjects.

The main conclusions are that increased consumption of sugar can increase caries activity and that the risk becomes greater the stronger the tendency for the sugar to be retained on the surfaces of the teeth. The risk is greatest if the sugar is eaten in a sticky form and between meals with resulting transient high concentrations of sugar on these surfaces. Under uniform conditions the increase in caries activity varies widely between individuals. When the intake of sugar is reduced the incidence of caries will fall but carious lesions may continue to appear even with a restricted intake of carbohydrate.—D. Harvey.

KITCHIN, P. C. and PERMAR, D. Results of an eight-year study of the effectiveness of carbohydrate restriction in reducing salivary lactobacillus counts. *J. Dent. Res.*, 1955, 34, 89-93. [Coll. Dent., Ohio State Univ., Columbus.]

Of 1089 patients, 811 had over 10,000 lactobacilli per ml. saliva and were deemed caries-active, as were later 101 of the remainder. Lactobacillus counts were reduced almost to zero after 2 weeks on diet 1, which contained about 100 g. carbohydrate daily. Successive diets 2, 3 and 4, containing increasing amounts of carbohydrate, 4 being almost unrestricted, were then given for 2-week periods provided the lactobacillus count remained low. Of the 811 patients in whom

caries was active, 410, 318, 225 and 142 completed the respective courses and at the end had low counts. After 6 months, 1 year, 2 years and 3 or more years on diet 4, in 91 of 126, 53 of 75, 25 of 34 and 14 of 23 patients counts remained low.

CARTER, W. J., JAY, P., SHELLE, I. L. and DANIEL, L. H. The effect of topical fluoride on dental caries experience in adult females of a military population. *J. Dent. Res.*, 1955, **34**, 73-76. [Res. Depts., Dental Dept., Great Lakes Naval Training Centre, Ill.]

Sixty U.S. Navy women had several thorough topical applications of 2 per cent. NaF solution and 88 had 0.9 per cent. NaCl solution. When they were re-examined after from 8 to 14 months, the difference between the groups in incidence of fresh caries was not significant. The NaF did not affect the salivary lactobacillus counts.

GIARDINO, G. and POLICE, P. Ricerca sul contenuto in fluoro dell'acqua potabile di Napoli. [Fluorine content of drinking water in Naples.] *Bol. Soc. ital. Biol. sper.*, 1954, **30**, 191-194. [Clin. Odontoiatrica, Univ. Naples.]

Fluorine was estimated by the method in "A.O.A.C. Methods of Analysis", 1945. Drinking water in Naples comes from springs in the territory of Serino, province of Avellino, with addition, especially in summer, of water from artesian wells in the city. The proportion of artesian-well water is greatest in the industrial area of the city, less in the centre of the city, and none in the old city (Vomero). The mean F content, in μg . per litre, for the 3 regions, respectively, is 225, 219 and 212. In water from the Serino springs it is 210. Water from the artesian wells was not tested separately. If 1 mg. per litre is taken as the concentration suitable for prophylaxis against dental caries, the Naples water had only one-fifth that required.—E. M. Hume.

4179

HILL, I. N., BLAYNEY, J. R. and WOLF, W. The Evanston dental caries study. 11. The caries experience rates of 12-, 13-, and 14-year-old children after exposure to fluoridated water for fifty-nine to seventy months. *J. Dent. Res.*, 1955, **34**, 77-88. [Walter G. Zoller Mem. Dent. Clin., Univ. Chicago, Ill.]

For parts 9 and 10 see Abst. 938, Vol. 23.

Part 7 concerned children after exposure for from 23 to 34 months (see Abst. 5366, Vol. 21).

The DMF rate per 100 children was reduced by about 21 per cent. for 12- and 13-, and by 12.5 per cent. for 14-year-old children in comparison with

the pre-treatment rates; the reductions were about double those which appeared after 2 years' treatment. For permanent molar teeth per 100 children the reductions in pit and fissure caries or fillings in occlusal surfaces were about 18.5 per cent. for 12- and 13-, and 12 per cent. for 14-year-old children. The number of occlusal surfaces free from caries or fillings increased by 49.7, 69.4 and 75.4 per cent. for the respective age groups. These data may be more closely correlated when they are stated on the basis of number of teeth. For permanent maxillary teeth the reduction of decayed and filled teeth per 100 children was thought not to be statistically significant for 14-year-old children, but might be so on the basis of number of teeth. The increase in immune permanent dentitions was significant only for the 13-year-old group.

The overall findings are considered to be significant and to show that a reduction in caries rates has occurred of 4 per cent. for each year of fluoridation.—D. Harvey.

4180

ZIMMERMANN, E. R. Fluoride and nonfluoride enamel opacities. *Pub. Health Rep., Washington*, 1954, **69**, 1115-1120. [Epidemiol. Branch, Nat. Inst. Dent. Res., Bethesda, Md.]

Children aged from 12 to 14 years were examined at Aurora, Illinois, where the F content of water is 1.8 p.p.m., and in Montgomery and Prince Georges Counties, Maryland, where tap water is almost devoid of F but where fluoridation was instituted 1 year before the examinations were made. Of those examined, 650 in Illinois and about 800 in Maryland, 352 and 220 children satisfied the criterion of having resided for all their lives in the respective districts. Opacities were classified in 2 main categories, as idiopathic white spots, non-fluoride in origin, or as fluorosis, questionable, very mild or mild in degree. The percentages of children unaffected or showing such opacities were, at Aurora, none 48, idiopathic 9, questionable fluorosis 26, very mild fluorosis 15, and mild fluorosis 2; in Maryland corresponding percentages were 64, 36, 0, 0 and 0.

Differentiation of the 2 types, idiopathic opacity and questionable fluorosis, is by appearance, idiopathic being usually as oval spots, the other tending to form horizontal striations; by distribution, idiopathic being not ordinarily in a definite pattern, the other being bilateral, and by extent, idiopathic affecting only 1 or 2 teeth, the other affecting several.—D. Harvey.

ADRIASOLA, G. and KAEMFFER, A. M. Algunos aspectos del primer programa de fluoración del agua potable en Chile. [Some aspects of the

N.A. and R., July 1955

first programme for adding fluorine to drinking water in Chile.] *Bol. Ofic. sanit. panamer.*, 1954, **37**, 66-75. [Escuela Salubridad, Univ. Chile.]

Dental examination of children aged from 3 to 12 years in San Fernando and Curico showed an average of 4.9 and 5.9 carious teeth per head in the two towns before the addition of F to the drinking water. In San Fernando 87.4 per cent. of the population used the public water supply and in Curico 92.7 per cent. In 1953, 1 p.p.m. F was added to the drinking water and a further dental examination will be made on children of the same age groups in 1956.—A. M. Copping.

4182

TAKAMORI, T., MIYANAGA, S., KAWAHARA, H., KONO, K., WAKATSUKI, H. and OKUSHI, I. [Dental fluorosis and skeletal changes in Aso-volcano district.] *Shikoku Acta Med.*, 1954, **5**, No. 4, 42-47. [Dept. Int. Med., Sch. Med., Tokushima Univ.] In Japanese: English summary.

For earlier work see Title 5069, Vol. 23.

In villages where the F content of drinking water was 1.1, between 0.7 and 0.8, or 0.2 p.p.m. slight myocardial damage in children was detected

by electrocardiograph and mottling of their teeth was recorded; in another area where the content was generally lower, mottling was less frequent or absent. [It is difficult to reconcile the conclusions with the data as tabulated].—D. Harvey.

4194

SINGH, I. Low-fat diet and therapeutic doses of insulin in diabetes mellitus. *Lancet*, 1955, **268**, 422-425.

Eighty patients with insulin-sensitive diabetes were treated with a diet containing 20 to 30 g. fat, 120 to 150 g. protein, and carbohydrate according to energy requirement. Insulin dosage was progressively reduced as patients became sugar-free at each level. Most of the patients did not require insulin after 3 to 6 weeks. Some patients were able to dispense with insulin after 18 weeks and some continued to require small doses. In a follow-up study of the patients no longer requiring insulin, serial glucose tolerance tests were made on 7, of whom 5 showed a return to normal.

GASTRO-INTESTINAL CONDITIONS

4197

HOLT, L. E. (Jr.). Nuevos puntos de vista en la alimentación del niño. [New points of view in infant feeding.] *Rev. española Pediat.*, 1954, **10**, 741-748. [New York Univ.-Bellevue Med. Centre.]

A discussion of results obtained by the author and his colleagues (see also Absts. 3658, 3659, Vol. 18; 5707, Vol. 20; Somersalo, O., *Amer. J. Dis. Child.*, 1952, **84**, 767), which suggest that in intestinal disorders, including diarrhoea and steatorrhoea, the amounts of fat and carbohydrate which are tolerated and absorbed are larger than was earlier thought.—D. Duncan.

4198

HAYES, M. A. Dietary control of the post-gastrectomy "dumping syndrome". *J. Amer. Dietetic Assoc.*, 1955, **31**, 133-137. [Samuel C. Harvey Metabol. Unit, Dept. Surg., Sch. Med., Yale Univ., New Haven, Conn.]

Seven cases of failure to gain weight, with or without postprandial distress, were treated satisfactorily with a diet high in fat and protein and

N.A. and R., July 1955

low in carbohydrate. The progress of the most severe case is described in detail. A satisfactory diet for such patients seems to be one in which the calories from carbohydrate, protein and fat are in the ratio 1 : 1.5 : 5.—F. C. Aitken.

4199

PAULSON, M. and HARVEY, J. C. **Hematological alterations after total gastrectomy: evolutionary sequences over a decade.** *J. Amer. Med. Assoc.*, 1954, **156**, 1556-1560. [Dept. Med., Johns Hopkins Univ., Baltimore, Md.]

The 27 patients studied haematologically after removal of the stomach were 21 men and 6 women, 18 negro and 9 white, mostly between 40 and 55 years old.

Fe deficiency anaemia developed shortly after operation as a result of oesophageal and duodenal erosion and slow bleeding, so Fe was given as a routine; this was considered to be responsible for a normal peripheral blood picture in 5 patients who died within a year after operation. Macrocytosis developed in 19 patients from 6 months to 7 years, but commonly 1 to 2 years, after operation. When patients lived long enough it was invariably followed by anaemia and later by the appearance of megaloblasts in the bone marrow. The condition responded to vitamin B₁₂ given parenterally in all 5 patients so treated.—D. Duncan.

4200

BOTHE, F. A., MAGEE, W. S. and DRISCOLL, R. H. **A massive resection of the small intestine from fifteen centimeters distal to the ligament of Treitz to within six centimeters of the ileocecal valve—with a four year follow-up.** *Ann. Surg.*, 1954, **140**, 755-758. [Philadelphia, Pa.]

The patient, now a man of 60, daily takes over 2 qt. milk, at least $\frac{1}{4}$ lb. cheese and, contrary to earlier recommendations (Absts. 4787, Vol. 8; 2620, Vol. 10) large quantities of butter. Diarrhoea is prevented by a mixture of Kaomagna and paregoric and avoidance of certain foods, e.g., stewed fruit. He works as a travelling salesman. His weight is only 10 lb. below that before operation and anaemia has not developed. Biochemical results at follow-up were: blood Ca 10.4 mg. per cent.; serum proteins in separate studies 6.4 and 6.7 g. per cent.; daily loss of fat in stools 15.3 g.

4201

DEKKERS, H. J. N. **De behandeling van lijders aan ulcus duodeni met koolhydraatrijk dieet.** [Treatment of patients with duodenal ulcer with carbohydrate-rich diet.] *Nederland. Tijdschr. Geneesk.*, 1955, **99**, 176-182. [Amsterdam.] English summary.

On the theory that it is the pain of duodenal

Vol. 26, No. 3

ulcer that is invaliding and that the pain is caused by gastric juice, a diet was devised to cause no gastric secretion, of water, tea, sugar, dry rusks, dry white bread, jam, syrup, honey, dry rice, fruit juices, potatoes, boiled leafy vegetables, raw lettuce with sugar and lemon, and the whites of one or two eggs daily. It is difficult to achieve a sufficient intake of energy on this diet for patients who are working, but it can be maintained for a few weeks. After three weeks 25 to 50 g. butter and 50 g. lean meat daily are allowed, and, if the patient wishes, 2 glasses of a mixture half milk, half water. The tests described lasted 6 months. Of 68 patients with duodenal ulcer, confirmed by X-ray, given this diet 22 received no drug; they were free of pain after 2 weeks and 15 remained so after 6 months; 7 were not seen again. Of the other 46, 37 had to be given antacids, in addition to the diet, either because of severe pain or because they could not be persuaded that the diet alone would help them. All improved and 31 were still free of pain after 6 months; 6 were not seen again. Nine patients did not react favourably to the diet.

From consideration of findings in concentration camps and during food shortage in Holland and of reports from other countries, the conclusion is drawn that a high standard of living may cause ulcers.—M. Eddison.

4202

HARDT, L. L. and STEIGMANN, F. **Improved antacid therapy of peptic ulcer.** *Amer. J. Digest. Dis.*, 1954, **21**, 353-357. [Stritch Sch. Med., Loyola Univ., Chicago, Ill.]

Satisfactory results in clinical trials with a new proprietary antacid mixture are reported.

GERRARD, J. W., ROSS, C. A. C. and SMELLIE, J. M. Coeliac disease. Results of late treatment with gluten-free wheat diet. *Lancet*, 1955, 268, 587-589. [Dept. Paediat., Univ. Saskatchewan.] Despite intervals of from 3 to 14 years between the diagnosis of coeliac disease and the beginning of treatment with gluten-free diet, the 18 children and adolescents, treated for from 4 to 25 months, responded with acceleration of growth in height and weight and disappearance of steatorrhoea. F. C. Aitken.

4207

HAEX, A. J. C. and LIPS, J. B. Nieuwe mogelijkheden bij de behandeling van spruw. [New possibilities for the treatment of sprue.] *Nederland. Tijdschr. Geneesk.*, 1955, 99, 102-106. [Acad. Ziekenhuis, Leyden.] English summary.

Steatorrhoea, without visible anatomical lesion, is the main sign of a group of diseases consisting of coeliac disease in children, tropical sprue and non-tropical sprue. Patients with non-tropical sprue seem often to have had coeliac disease in childhood or to have near relatives suffering from this disease. Steatorrhoea in these diseases gives rise to serious general upset, though fat absorption remains at 60 to 80 per cent. This is in contrast to steatorrhoea of pancreatic origin, which with a far smaller absorption of fats often gives only slight signs. Dicke, Weijers and van de Kamer (Title 5091, Vol. 23) have demonstrated that gluten from wheat plays an important part in coeliac disease, and report success in its treatment with a gluten-free diet. This led to experimental treatment with gluten-free diet of a patient seriously ill with steatorrhoea for which all possible diagnosis except sprue had been excluded. Usual modes of treatment, continued for 6 years, gave

no improvement. Treatment with ACTH did give some improvement, but as this treatment would have to be continued indefinitely, an experiment with a gluten-free diet seemed justified. After 3 or 4 weeks of a diet completely free of gluten, all symptoms and signs had disappeared. They returned when, experimentally, some wheat products were added to the diet.—M. Eddison.

OEHME, J., SUCKOW, J. and DITTRICH, J. K. Zur Symptomatologie und glutenfreien Therapie der einheimischen Sprue. [Symptomatology and treatment by gluten-free diet of non-tropical sprue.] *Deutsch. Ztschr. Verdauungs- u. Stoffwechselerk.*, 1954, 14, 257-263. [Kinderklin., Univ. Leipzig.]

In the introduction the relation between diseases of the digestive tract, the nervous system and the blood is discussed. The case history is then given of a 15½-year-old girl, admitted to the clinic with obvious tetany and a blood condition resembling pernicious anaemia. She had been in hospital twice before, first at the age of 8 elsewhere; the diagnosis had then been abdominal tuberculosis. In 1952 she had been admitted to the university clinic. She was then 35 cm. below the average height for her age and 2.8 kg. too light for her size, and showed severe hyperchromic anaemia. Vitamin B₁₂ gave a reticulocyte crisis after 8 days and after this a considerable improvement in the blood.

When admitted to the clinic in 1954 there was no gastro-intestinal upset apart from an occasional attack of "doughlike" diarrhoea. X-ray photographs showed abnormalities in motility, tonus and secretion of the digestive tract. This led to the diagnosis of non-tropical sprue [there is no mention of steatorrhoea]. A gluten-free diet was given, with good results. Calcium and later Antitetanin was given for the tetany, vitamin B₁₂ for the anaemia and pepsin for anacidity. In 50 days the patient gained 7.2 kg. on the gluten-free diet; in 1952 she had gained only 2.7 kg. in 50 days on a normal diet.—M. Eddison.

BARR, M., DELAVA, S. and ZETTERSTRÖM, R. Studies of the anemia in ulcerative colitis with special reference to the iron metabolism. *Acta paediat.*, 1955, 44, 62-72. [Paediat. Clin., Karolinska Sjukhuset, Stockholm.] French, German and Spanish summaries.

The subjects were 9 children, aged 6 to 16 years, with typical ulcerative colitis. Most of them had normochromic anaemia, 2 had hypochromic anaemia and all had low serum Fe values. Blood transfusions and intravenous saccharated iron oxide produced only slight improvement. There

N.A. and R., July 1955

was no firm correlation between the degree of anaemia and the loss of blood in stools.

Total Fe-binding capacity was variable, but usually below normal. Absorption of 25 mg. Fe labelled with ^{59}Fe was high, ranging from 8 to 56 per cent., but usually only a small proportion was used for Hb formation.

It is concluded that a primary increase in Fe storage or a failure of bone marrow function may be the main cause of anaemia in ulcerative colitis. Spontaneous improvement of the anaemia may be expected when remission of the primary condition occurs.—D. Duncan.

THYROID DISEASE

SCHAMAUN, H. M. and BAUMANN, T. Über die Behandlung der Struma congenita mit Thyroxin "Roche". [Treatment of congenital goitre with thyroxine Roche.] *Helv. paediat. Acta*, 1954, **9**, 449-454. [Kinderspital, Aarau.] French, Italian and English summaries.

Between 1945 and 1952, 30 newborn or very young babies with congenital goitre and without signs of hypothyroidism were treated with thyroxine. Eleven belonged to grade 2, 5 to grade 4 and others to intermediate overlapping grades according to the Swiss Goitre Commission's system of classification. The children were given thyroxine equivalent to from 325 to 1950 μg . total I. In 16 the goitre disappeared completely; in 13 it decreased greatly; in one, only a slight decrease occurred. There was no harmful effect apart from occasional mild diarrhoea which soon disappeared. M. Eddison.

4212

SCHAMAUN, H. M. Pathologisch-anatomische Untersuchungen über die Struma congenita im Kanton Aargau 1940-1951. [Studies in the pathological anatomy of congenital goitre in Kanton Aargau, 1940-1951.] *Helv. paediat. Acta*, 1954, **9**, 455-475. [Kinderspital, Aarau.] French, Italian and English summaries.

Theories of goitre formation are considered.

Reports on congenital goitre in the canton of Aargau were studied for the period from 1940 to 1952 before the prophylactic use of iodine in salt, which began in 1952. Before 1940 the size of the thyroid was not always accurately recorded at post-mortem examinations of infants. Data were available for 325 stillborn and newly born infants measuring at least 45 cm.; 174 were boys and 151 girls. The glands were classified according to size and ranged from under 3 g. to over 20 g.,

those up to 3 g. being considered normal. The percentage of infants with glands weighing more than 3 g. fell from 77.8 in 1940-42 to 29.4 in 1949-51; those of over 6 g. dropped from 33.3 to 6.4 per cent. The average relative thyroid weight fell from 2.52 to 1.13 g. per kg. bodyweight. Enlargement of the heart and hyperplasia of the thymus gland were often found to accompany the goitre, most frequently when the thyroid gland weighed more than 6 g.

There was a spontaneous decrease in numbers of goitre patients other than infants; it was seen also in youths registering for military service, the incidence falling from 10 per cent. in 1939-40 to 2.5 per cent. in 1947. That decrease is attributed to a general improvement in hygiene and nutrition. M. Eddison.

4213

SOLLGRUBER, K. Zum Problem der Säuglingsstruma. [Goitre in infants.] *Öst. Ztschr. Kinderheilk.*, 1954, **10**, 312-315. [Moosmähldstr. 14, Dornbirn, Vorarlberg.]

Among 4800 infants examined since 1943 in the ward for the newborn at the hospital, the average percentage with goitre was 7. In the last 2 years the percentage has been 11 and in the first quarter of 1954, 20. The sexes were equally affected. Treatment has been given from the third day of life with large doses of iodine spread over several days. The use of iodised salt by the people is strongly recommended, but ignorance of the need is common. It is considered that iodised table salt should be on sale everywhere as the rule, and that untreated salt should be available only on special application.—E. M. Hume.

4214

SAXÉN, E. A. and SAXÉN, L. O. Mortality from thyroid diseases in an endemic goitre area. Studies in Finland. *Doc. Med. geogr. trop.*, 1954, **6**, 335-341. [Lab. Pathol., Central Inst. Radiotherap., Helsinki.]

The distribution in Finland of deaths from thyroid cancer, malignant goitre, exophthalmic goitre and toxic goitre were compared with the distribution of endemic goitre. Only the deaths from toxic goitre seemed to be significantly higher in the rural areas where there was high frequency of endemic goitre.—E. M. Hume.

SILVA, W. and BORGES, P. Incidência do bócio em escolares nas cidades de Cuiabá, Goiânia e Goiás—1952. [Incidence of goitre in school children in the towns of Cuiabá, Goiânia and Goiás in 1952.] *Univ. Brasil Inst. Nutrição Trab. e Pesq.*, 1952, **5**, 19-40. English summary.

The percentage incidence of endemic goitre in

schoolchildren from the 3 Brazilian towns was 71.09, 66.62 and 81.07. The incidence was higher among the coloured than the white children, in girls than in boys, in the country than in the towns, in public than in private schools, in lower than in upper economic groups and in Indian than in other communities. Iodine deficiency is thought to be the cause. (From summary.)—A. Hepburn.

ANAEMIA

- 4216
VAHLQUIST, B. Prematuridad y anemia. [Prematurity and anaemia.] *Rev. española Pediat.*, 1954, 10, 645-650. [Clin. Paediat., Univ. Upsala.] French, English and German summaries.

The types of anaemia met in the premature infant during the first weeks of life are discussed. The initial fall in Hb and red cell count which is usually seen is not fully understood and does not respond to the known methods of treatment for anaemia. Hypochromic microcytic anaemia responding to Fe may also occur, as well as the types of anaemia seen in full-term infants.—D. Duncan.

- 4217
POROWALLA, J. N. and RANGAM, C. M. Pattern of anaemias in infants of Central India. *Indian J. Pediat.*, 1955, 22, 1-4. [Dept. Paediat., Mahatma Gandhi Mem. Med. Coll., Indore.]

A haematological study was made of 100 infants under 2 years of age, with less than 10 g. Hb per 100 ml. blood. Infants who were wholly breast fed weighed, on the average, 67.8 per cent. of the expected bodyweight and had 8.94 g. Hb per 100 ml. blood; for infants on mixed feeding the values were 62.2 per cent. and 7.49 g. Hb. Thirty had tuberculosis, 21 diarrhoea and vomiting, 22 non-tubercular respiratory infections. Besides the 30 with active tuberculosis, 36 others were Mantoux-positive.

The infants not entirely breast fed received foods such as dal, roti (home-made bread) and rice, with a negligible Fe content. Data for the blood pictures are tabulated. Only one infant showed an appreciable number of megaloblasts in the bone marrow. It is concluded that the anaemia of infants in Central India is usually normocytic and hypochromic and is associated with Fe deficiency. Tuberculosis has an important contributory influence.—D. Duncan.

- SCOTT, E. M., WRIGHT, R. C. and HANAN, B. T. Anemia in Alaskan Eskimos. *J. Nutrition*, 1955, 55, 137-149. [Arctic Health Res. Centre, Pub. Health Serv., Anchorage, Alaska.]

The study was made on 297 Northern and 418 Southern Eskimos and on 110 white soldiers who were stationed near Anchorage. Mean Hb values and standard deviations were, respectively, 14.91 \pm 1.06, 14.60 \pm 1.19 and 15.76 \pm 1.23 g. Hb. per 100 ml. blood. Values for serum Fe were lower and for serum Cu higher in Eskimos and Aleuts than in the white subjects. The inhabitants of 4 villages were chosen for more intensive study. In 3 villages mean values for Hb for all age groups were low; those in the fourth were higher than in these. In 2 of the 3 villages the degree of anaemia was moderate, with a tendency to microcytosis; in the third the tendency was not apparent.

A therapeutic trial was made in one village; the inhabitants were given pills of FeSO₄, calcium lactate or ascorbic acid. Serum Fe was increased by each supplement, most by FeSO₄, but changes in Hb were small and variable.

The available foods are considered in relation to these findings as well as the family connections existing between the inhabitants of the villages. Deficiency of Fe with some other, as yet unidentified, cause is thought likely to account for the mild degree of anaemia.—D. Harvey.

MOORE, C. V. The importance of nutritional factors in the pathogenesis of iron-deficiency anemia. *Amer. J. Clin. Nutr.*, 1955, 3, 3-10. [Dept. Int. Med., Sch. Med., Washington Univ., St. Louis 10, Mo.]

On the basis that about 5 to 10 per cent. of food iron is assimilated by normal adults, daily retention from a diet containing 12 to 15 mg. Fe would be about 0.6 to 1.5 mg. The amount of Fe lost from the body in all ways other than in blood is estimated to be about 0.5 to 1.0 mg. daily. An adult man or post-menopausal woman would not readily become anaemic on account of poor intake or absorption of Fe. It is calculated that if they absorbed no Fe and excreted 1 mg. daily, 6 and 4 years, respectively, would be required before they would have only 7.5 g. Hb per 100 ml. The positions of the menstruating woman, whose monthly loss of Fe in blood is of the order of 14 to 28 mg., and of the growing child, are more precarious.

WILL, J. J. and VILTER, R. W. A study of the absorption and utilization of an iron chelate in iron-deficient patients. *J. Lab. Clin. Med.*, 1954, 44, 499-505. [Dept. Int. Med., Coll. Med., Univ. Cincinnati, Ohio.]

As judged by reticulocyte response and Hb regeneration in patients with hypochromic anaemia and from isotopic Fe absorption studies in normal subjects and subjects with hypochromic anaemia, absorption and utilisation of Fe from ferrie sodium versenate were no better than from ferrous sulphate.—F. C. Aitken.

4223

FISHER, M. and BIGGS, R. Iron deficiency in pregnancy. *Brit. Med. J.*, 1955, i, 385-386. [Health Dept., City of Oxford.]

The so-called physiological anaemia of pregnancy was prevented in 92 out of 104 patients by daily administration of iron throughout pregnancy. It is suggested that iron should be given as a routine to all pregnant women.—F. C. Aitken.

4224

HAWKINS, C. F. Value of serum iron levels in assessing effect of haematinics in the macrocytic anaemias. *Brit. Med. J.*, 1955, i, 383-385. [United Birmingham Hosps.]

Serum iron was estimated in samples from 100 patients before and after treatment, usually with vitamin B₁₂ or folic acid by injection. Macrocytic anaemias of all types were included.

In 60 patients treatment was successful, and the serum Fe level fell. In 32 out of 33 samples taken 48 hr. after successful treatment the mean fall in serum Fe was 105 µg. per 100 ml. Whatever the original level the values tended to fall to about 50 or 60 µg. per 100 ml. and to remain there until the blood count returned to normal. Impending Fe deficiency was indicated when the level was 40 µg. per 100 ml. or less. No fall in serum Fe occurred in the 40 patients in whom the treatment was ineffective, or in 12 normal subjects given injections of vitamin B₁₂ or folic acid.

The 48-hr. serum Fe test is considered a reliable method of assessing the effect of treatment in macrocytic anaemia.—D. Duncan.

NATIONAL RESEARCH COUNCIL, FOOD AND NUTRITION BOARD, WASHINGTON. Sodium-restricted diets. The rationale, complications, and practical aspects of their use. *Div. Biol. Agric., Nat. Res. Council, Publ. No. 325*, July 1954, pp. vi + 71.

About half of this important report of the Food and Nutrition Board of the National Research Council consists of documented chapters on normal sodium metabolism; the use of sodium-restricted diets to treat different disorders; the accompanying risks of producing sodium depletion or other deficiency states; the planning of sodium-restricted diets, with a table of nutrients provided by a standard 500-mg.-sodium diet, and hints on flavouring; the sodium contents of foods and drinking waters; methods of estimating small quantities of sodium in foods; and salt substitutes. A comprehensive 17-page table of the

sodium and potassium contents of foods and a condensed derived table of the estimated best values for sodium content follow. The other tables include one of towns in the United States where the drinking water is known to contain over 2.0 mg. Na per 100 g.; this may affect the sodium content of cooked or canned foods, soft drinks and beer.

Information about the sodium content of many foods is inadequate, owing either to natural variation or to the failure of manufacturers to make precise statements on their labels. Since it is the sodium content that is vital, such terms as "salt-poor diet" or "salt-free food" should be dropped.—W. M. Deans.

4229

CLIFFORD, P. A. Sodium content of foods. *J. Amer. Dietetic Assoc.*, 1955, **31**, 21-27. [Div. Food, Food and Drug Admin., Washington, D.C.]

VAN STEENIS, P. B. Levercirrhose bij gerepatrieerden uit Indonesië. [Cirrhosis of the liver in repatriates from Indonesia.] *Nederland. Tijdschr. Geneesk.*, 1955, **99**, 166-173. [Amsterdam.]

Out of 3500 patients repatriated since the war, 18 were diagnosed as suffering from cirrhosis of the liver. Two case histories are discussed to illustrate difficulties of diagnosis. All had suffered from temporary serious malnutrition. In the tropics cirrhosis occurs mostly in Indonesian men, though for religious reasons they drink no alcohol. In 1931 Professor Bonne published statistics for the east coast of Sumatra showing that out of 10,000 people, 3.1 Indonesian men over 18 died of cirrhosis, as against 1.8 Chinese over 28 and 0.39 Dutch of all ages, these being, respectively, 4.29, 1.85 and 0.54 per cent. of the total death rate.

Cirrhosis is discussed in relation to kwashiorkor and hepatitis. High-protein diet, especially with milk, is the treatment of choice. Fruit is helpful. Drugs, isolated amino-acids and synthetic vitamins are not recommended.—M. Eddison.

4231

GOODMAN, J. I. The relationship of obesity to chronic disease. *Geriatrics*, 1955, **10**, 78-82. [Med. Sch., Western Reserve Univ., Cleveland, Ohio.]

Of 1219 patients in hospital with chronic disease 12 per cent. were obese. One out of every 3 obese patients had enlargement of the liver and 75 per

cent. had high blood pressure. Weight reduction was achieved by diet treatment in two-thirds of the obese patients, but in only one-third of the patients was the effect permanent. Weight reduction was accompanied by reduction of blood pressure and a return of the liver to normal size. The incidence of diabetes, amputations and cardiac failure was higher in obese than in non-obese patients.—F. C. Aitken.

HATCH, F. T., WERTHEIM, A. R., BURMAN, G. H., WATKIN, D. M., FROEB, H. F. and ERSTEIN, H. A. (with MCPHEE, G., ENGLISH, S. and DAYTON, J.) Effects of diet in essential hypertension. 3. Alterations in sodium chloride, protein and fat intake. *Amer. J. Med.*, 1954, **17**, 499-513. [Res. Serv., Columbia Univ., New York.]

A group of 47 patients, whose blood pressure did not decrease significantly during a control period in hospital, were used in this study of the effect of adding supplements to the Kempner rice diet in the treatment of essential hypertension. In patients who responded favourably to the unmodified rice diet no loss of beneficial effects was seen when 0.5 g. NaCl, 12 to 50 g. low-Na protein, 20 to 40 g. fat or 200 g. vegetable daily was added. Larger additions of NaCl usually evoked significant rises of blood pressure. A special low-Na diet which incorporated many of the modifications of the basic rice diet was tested and is recommended for hospital maintenance of patients who have responded to the Kempner diet. (For parts 1 and 2 see *Amer. J. Med.*, 1950, **9**, 428; 441.)

GOULDER, N. E., KISSANE, R. W. and BOHL, R. W. Provocative aspects of lipotropic therapy in angina pectoris. *Amer. Heart J.*, 1954, **48**, 906-913. [Div. Cardiol., Dept. Med., Coll. Med., Ohio State Univ., Columbus.]

Of 25 patients treated with a soya lecithin preparation 6 showed clinical improvement which was not maintained when treatment was discontinued. In response to treatment serum cholesterol and phospholipin levels fell and the ratio of serum cholesterol to phospholipins increased. The changes were of greater degree in those patients who showed clinical improvement. These values tended to return towards normal while patients were undergoing treatment.—F. C. Aitken.

4237

RUSSELL, A. and YOUNG, W. F. Severe idiopathic infantile hypercalcaemia. Long-term response of 2 cases to low calcium diet. *Proc. Roy. Soc. Med.*, 1954, **47**, 1036-1040. [Queen Elizabeth Hosp. Child., London.]

Two mentally and physically retarded infants with serum calcium levels of 14.5 and 14 to 14.6 mg. per 100 ml. are described. They were treated with a low-Ca diet with soya bean flour (Soylac) in place of milk.

The serum Ca fell to 9.5 mg. per 100 ml. in the infant so fed for 14 weeks, and remained normal; blood urea also fell to normal and there was clinical improvement which persisted when the normal diet was restored. In the second infant the diet could be given for only 4 weeks, during which the serum Ca fell to 10.5 mg. per 100 ml., but blood urea remained high. Subsequent progress was slow, and serum Ca was normal but urea still high at 2½ years of age.

The etiology of the condition and its possible relation to vitamin D excess are discussed.

D. Duncan.

4238

KESSLER, E. Hypercalcemia and renal insufficiency secondary to excessive milk and alkali intake. *Ann. Int. Med.*, 1955, **42**, 324-338. [Med. Serv., Veterans Admin. Hosp., Albany, N.Y.]

Three cases are described and discussed with 18 previously reported by other workers. Treatment in all recorded cases was by giving a low-Ca diet and withholding absorbable alkali. Improvement resulted in most.—F. C. Aitken.

4239

LEEDHAM, J. N. Glutamic acid in the treatment of mental deficiency. *Med. Officer*, 1955, **93**, 117-122; 133-137. [Dept. Pub. Health, Bradford.]

The subjects were 12 pairs of children mentally handicapped in different ways, with ages ranging

from 4½ to 17½ years and intelligence quotients mostly between 30 and 60. For 6 months one of each pair had 10 g. glutamic acid daily in powder form, the other saccharine lactate.

Intelligence and performance tests before and after revealed no significant difference between the groups. However, many of the parents of children who had glutamic acid reported that they seemed more energetic than before.

The second instalment consists of a detailed discussion of the literature. A large scale trial, particularly with borderline or educationally backward children, would seem desirable, since among them even a small improvement would yield great social and economic results.

W. M. Deans.

4240

WOOLF, L. I., GRIFFITHS, R. and MONCRIEFF, A. Treatment of phenylketonuria with a diet low in phenylalanine. *Brit. Med. J.*, 1955, **i**, 57-64. [Hosp. Sick Child., Great Ormond St., London.]

The passage of an acid hydrolysate of casein through charcoal removed phenylalanine, tyrosine and tryptophan. The residual amino-acids with additions of tyrosine, tryptophan and milk were the principal sources of amino-acids in a diet given to 3 mentally defective children with phenylketonuria. Phenylpyruvic acid disappeared from the urine and general intelligence increased in all 3, most improvement occurring in the 2 younger children, each aged about 2 years 8 months before treatment lasting 9 and 10 months. The initial effect on the third child aged 5 years and 4 months was striking.—A. Hepburn.

4241

WISSLER, H., GAUTIER, R. and LINDER, A. Über die Gewichtszunahme von Kindern verschiedener Altersstufen bei Mast. Beitrag zum Problem der Fettsucht. [Weight increase of children of different ages when fattened. The problem of obesity.] *Helv. paediat. Acta*, 1954, **9**, 524-529. [Kindersanat. Pro Juventute, Davos.] French, Italian and English summaries.

The increase in weight of 480 children during 3 months' stay in a sanatorium was analysed. Children who had been seriously ill with pulmonary disease before admission were excluded from the analyses. Their daily timetable consisted of 2½ to 3 hr. at rest, 3 to 4 hr. at school, 1 hr. walking; the rest of the day was spent in their individual occupations and in eating. The amount of food taken, though difficult to estimate, was probably about 130 per cent. of the normal energy intake. The children were divided into 4 age groups, 2 to 5, 6 to 9, 10 to 12 and 13 to 16 years. The weight increases for the groups, as percentages of original

weight, were, respectively, 6.3, 6.2, 9.7 and 9.6. In the lower age groups boys and girls showed no difference, but in the age group 13 to 16 years the girls increased more than the boys, 10.6 and 8.6 per cent., respectively.—M. Eddison.

4242

6. FEEDING OF ANIMALS

GENERAL, INCLUDING DIGESTIBILITY TRIALS

4243

CRASEMANN, E. Neuere Ergebnisse von Respirationsversuchen. [Recent results of respiration experiments.] *Landwirtsch. Forsch., Suppl.* 5, pp. 13-28. [Inst. Haustierernährung, Eidg. Tech. Hochschule, Zürich.] English summary.

This lecture summarises and discusses the technique of estimating energy production value of feedingstuffs. The use of different experiments is discussed and the suggestion is made that the ratio between net energy as a percentage of metabolisable energy when protein and fat are laid down (growth) to that when only fat is laid down may be of importance. Breirem (Absts. 1090, Vol. 10; 3508, Vol. 5) found in respiration experiments with pigs that there was more loss of energy as heat during growth than during fattening, i.e., a lower ratio of net to metabolisable energy, which is the reverse of what is commonly found with farm and laboratory animals.

A table summarises data to compare the net calories for fattening (NK_F) and the ratio of net to metabolisable energy of 1 kg. digested starch, fat and protein in cattle, sheep, rabbit, pig and fowl. Finally the Kellner "Wertigkeit", the ratio of observed to computed net energy, is discussed with reference to the possible effect of fibre and the desirability of respiration experiments sufficiently numerous to permit of statistical analysis.—I. Leitch.

4244

FUCHS, P. Prinzipien der absoluten Futterwertmessung. [Principles of measuring absolute feeding value.] *Arch. Tierernährung*, 1954, No. 5, Beihefte, 182-196. [Böhlitz, Ehrenberg, Leipzig.]

The arguments presented in an earlier paper (Abst. 2791, Vol. 21) are presented afresh without much change. A footnote discusses the proposal

by Nehring (Abst. 2816, Vol. 25) to make the Kellner unit (K.E.) 2500 Cal. There would be advantages of ease of arithmetical manipulation, but from that point of view the ideal would be a unit of 1000 Cal., which would be entirely divorced from Kellner's work.

The crux of the matter is that the productive value of any feed is different for different species of animal and must be estimated for each. And then the value is valid only for fat production.

I. Leitch.

4245

WALKER, D. M. and HEPBURN, W. R. The nutritive value of roughages for sheep. 1. The relationship between the gross digestible energy and the chemical composition of hays. *J. Agric. Sci.*, 1955, 45, 298-310. [Rowett Res. Inst., Bucksburn, Aberdeenshire.]

With 3 groups of 3 Cheviot lambs, 4 months old, the relationship between gross digestible energy (G.D.E.) and the proximate constituents found by chemical analysis of 24 hays was studied. Each hay was given to one of the groups of lambs for a preliminary period of 10 days and a similar collection period in metabolism crates. There was a high negative correlation between percentage G.D.E. and crude fibre, lignin and cellulose, but there was no advantage in analysing for the last 2. Crude fibre estimated by digestion with 5 per cent. H₂SO₄ was closely related to digestibility of energy, and metabolisable energy to percentage G.D.E. When starch equivalent was calculated from G.D.E., the values were always lower than conventional values.—T. D. Bell.

4246

CRASEMANN, E. Die Fettansatzwirkung der Futtermittel bei verschiedenen Nutztierarten und ihre Bedeutung für das Messen des Futterwertes. [Fattening value of feeds in different

N.A. and R., July 1955

farm animals and its significance for the measurement of feeding value.] *Wiss. Abh. Deutsch. Akad. Landwirtschaft. (Berlin)*, 1954, 5, 141-164. [Inst. Haustierernährung, Eidg. Tech. Hochschule, Zürich.] English summary.

Methods of evaluating feedingstuffs, the units in which feeding value is expressed, and the possibility of extending the production equivalent of Møllgaard and Breirem, estimated with bullocks, to other species, are critically discussed, with references.

A table is given of the fattening effect of starch, fat and protein for bullock, sheep, rabbit, pig and poultry. The relative efficiency of the conversion of energy from fat or protein into energy of body fat is much the same for the first 4 species, and the slightly higher values for poultry are of no practical importance. That the fattening effects of the different nutrients given separately or mixed or in the form of a feedingstuff are additive was shown by Kellner and Fingerling for the bullock and the pig; recent experiments suggest that this is true also for sheep and poultry; it has not yet been demonstrated for the rabbit. Another table gives coefficients for applying Møllgaard's NK_F values, established with the bullock, to fattening sheep, rabbit, pig and poultry, with an example of their use; the results are also given in terms of starch equivalents.

All this applies only to highly digestible feedingstuffs low in fibre. Difficulties arising from differences in the capacity of different species to digest fibre may eventually be overcome, but the prospect of dealing with those due to species differences in Kellner's "value" (*Wertigkeit*) seems less hopeful.

W. M. Deans.

4247

ARMSTRONG, D. G., PRESTON, T. R. and ARMSTRONG, R. H. Digestibility of a sample of pasture grass by calves. *Nature*, 1954, 174, 1182-1183. [Sch. Agric., King's Coll., Univ. Durham.]

Pasture grass, cold-stored at 0° to 5° F., was given to 4 calves aged from 10 to 12 weeks and the digestibility of the proximate nutrients was estimated over a 10-day collection period by conventional and faecal-index methods, using chromium oxide. Lignin and cellulose were also estimated, and the mean digestibility coefficients were: dry matter 75.0, organic matter 77.1, crude protein 59.8, ether extractives 45.6, crude fibre 79.7, N-free extractives 82.9, cellulose 84.0, and lignin, 3.0. The mean percentage recovery of chromium oxide was 102.3 ± 1.93 .—D. M. Walker.

4248

MAYMONE, B., PETRUCCI, E. and TIBERIO, M. Ricerche sulla produttività e sul valore nutritivo di una Polygonacea della flora spontanea, resistente alla siccità: *Polygonum romanum* Jacq. [The yield and nutritive value of a native plant resistant to drought, *Polygonum romanum*, Jacq.] *Ann. Sper. agrar.*, 1953, 7, 647-673. [Ist. Sper. Zootec., Rome.] English summary.

Polygonum romanum, Jacq., a herb which commonly occurs naturally in pastures round Rome, is relished by grazing stock, and is very resistant to drought, flowering in the late summer. Samples at 2 stages of growth were analysed and tested for digestibility. The ash contained more Mg than usual, but did not seem to upset the animals used in the trials. The plants at the beginning of flowering and in full flower had the following composition, respectively (mean percentage digestibility in brackets): dry matter 32.14, 38.78 (57.06); crude protein 3.80, 3.85 (42.91); ether extract 1.00, 0.76 (57.74); crude fibre 10.70, 11.20 (47.42); ash 2.57, 2.31; N-free extract 14.07, 20.66 (70.43). In digestible nutrients it was similar to timothy grass.—T. D. Bell.

4249

MAYMONE, B., DATILLO, M. and MAZZIOTTI DI CELSO, P. Ricerche sulla produttività e sul valore nutritivo della leguminosa *Scorpiurus muricata* L. var. *subvillosa* (L.), pregevole foraggiera dei prati naturali e dei pascoli meridionali. [The productivity and nutritive value of the legume *Scorpiurus muricata*, L., var. *subvillosa* (L.), a forage plant of natural meadows and pastures in the South.] *Ann. Sper. agrar.*, 1953, 7, 1289-1329. [Ist. Sper. Zootec., Rome.] English summary.

Scorpiurus muricata, L., var. *subvillosa* (L.) is an annual legume which readily sets seed and occurs naturally in the pastures of the Campagna romana. It is held in high esteem by local shepherds. Attempts to establish it in pastures on the experimental farm were successful in 4 years' trials. It was found to give a high yield of dry matter per acre with a good protein percentage. Its digestibility by sheep was higher than that reported for alfalfa and red clover.—T. D. Bell.

4250

MAYMONE, B., PETRUCCI, E. and BATTAGLINI, A. Ricerche sulla produttività e sull'elevato valore nutritivo di *Helminthia echinoides* (L.) Gaertn., Composita infestante nel bacino del Mediterraneo. [The productivity and high nutritive value of *Helminthia echinoides*, (L.) Gaertn., one of the Compositae infesting (pastures) in the Mediterranean basin.] *Ann. Sper. agrar.*, 1953, 7, 1331-1366. [Ist. Sper. Zootec., Rome.] English summary.

Helminthia echinoides, (L.) Gaertn. is regarded as a weed very common in natural pastures and in

stubbles. It is readily eaten by grazing stock. Chemical analysis of the plant at the early flowering stage, when a good yield of dry matter was obtained, showed that in protein content and digestibility by sheep, it was comparable to alfalfa. The digestibility rapidly declined as flowering advanced, but remained comparable to that of common fodders such as red clover at a similar stage of growth.—T. D. Bell.

4251

MAYMONE, B. and BATTAGLINI, A. Ricerche sulla digeribilità e sul valore nutritivo dei semi di carrubo (*Ceratonia siliqua* L.). [The digestibility and nutritive value of carob beans (*Ceratonia siliqua*, L.).] Ricerche sulla digeribilità e sul valore nutritivo del "germe" di carruba (*Ceratonia siliqua* L.). [The digestibility and nutritive value of carob bean germ (*Ceratonia siliqua*, L.).] Ricerche sul valore nutritivo delle polpe di carrube esaurite, residue dalla preparazione industriale dell'alcool. [The nutritive value of extracted carob bean pulp residues from the industrial production of alcohol.] *Ann. Sper. agrar.*, 1953, 7, 1367-1375; 1977-1984; 1985-1999. [Ist. Sper. Zootec., Rome.] English summary.

The composition of the dry matter of the carob bean seeds (with digestibility by sheep given in brackets) was: crude protein 18.5 (67.0), ether extract 2.0 (70.5), crude fibre 3.0 (64.8), ash 3.5 and N-free extract 68.0 (87.8) per cent. Comparison with other values reported shows a wide variation depending on the variety and source of the seed.

The composition of the dry matter, and the digestibility, of the germ or embryo and cotyledons of the seed were: crude protein 40 (81), ether extract 3.5 (83), crude fibre 8 (75), ash 5.6 and N-free extract 33 (84) per cent. Here the variation between varieties and sources was slight.

The pulp obtained after industrial processing for the extraction of alcohol had a satisfactory chemical analysis, but was nearly indigestible, and was not readily accepted by animals.

T. D. Bell.

4252

MAYMONE, B., TRIULZI, G. A. and TIBERIO, M. Ricerche sulla digeribilità e sul valore nutritivo della produzione foraggera autunno-invernale dei prati naturali e dei pascoli centro-meridionali. [The digestibility and nutritive value of autumn and winter forage produced in the central-southern natural meadows and pastures.] *Ann. Sper. agrar.*, 1953, 7, 2027-2040. [Ist. Sper. Zootec., Rome.] English summary.

The natural pastures of central and southern Italy in autumn and winter are similar in chemical composition and digestibility to spring and summer

pastures in Germany and Sweden. There is a greater difference between the hill and the lowland pastures, owing to differences of soil rather than of botanical composition.—T. D. Bell.

4253

MAYMONE, B. and TIBERIO, M. Ricerche sulla digeribilità e sul valore nutritivo delle crisalidi sgrassate di *Bombyx mori*. [The digestibility and nutritive value of defatted chrysalides of *Bombyx mori*.] *Ann. Sper. agrar.*, 1954, 8, 203-228. [Ist. Sper. Zootec., Rome.] English summary.

After the silk has been removed the fat is extracted from the chrysalides of the silkworm, and the defatted chrysalides can be ground and used as a valuable source of protein in concentrates for stock. Chemical analysis of the meal gave the following percentage composition of the dry matter: crude protein 70 to 75, true protein 65 to 70, ether extract 4 to 9.5, crude fibre 5 to 8, ash 4 to 6.5 and N-free extract 9 to 10. There was great variation in the ether extract, depending on the original method of extraction. The ash had high P and S contents. The protein was of high biological value and contained all the essential amino-acids. It was superior to fishmeal, meat-meal and tankage in cystine, tyrosine, tryptophan, lysine and glutamic acid. In trials with sheep the following digestibilities were found: crude protein 87.7, true protein 87.0, ether extract 94.6, crude fibre 73.5 and N-free extract 36.2 per cent.

T. D. Bell.

4254

McCULLOUGH, M. E., BAIRD, D. M. and SELL, O. E. The relationship between forage dry matter digestibility and weight gain by dairy heifers on three winter grazing crops. *J. Dairy Sci.*, 1954, 37, 1435-1438. [Georgia Agric. Exp. Stat., Experiment.]

The forages used were Abruzzi rye, Arlington oats and Chapel hill rescue grass. Two one-acre plots of each forage were sown in September 1953. An 18-week grazing trial of three 6-week periods was begun in January 1954, with 9 dairy heifers. Fortnightly weights were recorded. Faeces were sampled and digestibilities of dry matter of the forages were estimated by the chromogen method. Analyses of hand-clipped samples of the forages were also made. Non-significant correlations were obtained between dry matter digestibility and average daily gain. It was concluded that digestibility of dry matter did not limit weight gain until the forages began to mature in early spring. The average daily gains of the heifers on rye, oats and rescue grass were, respectively, 1.64, 1.91 and 1.63 lb. The average dry matter digestibilities of the forages were rye 73.5, oats 73.9 and rescue grass 74.7 per cent.—J. N. Aitken.

N.A. and R., July 1955

4255

DIJKSTRA, N. D. and FRENS, A. M. De verteerbaarheid en voedervaarde van de perskoek van boegroemakka-pitten. [The digestibility and feeding value of the expeller cake of boegroemakka palm kernels.] *Landbouwk. Tijdschr.*, 1954, **66**, 634-638. [Rijkslandbouwproefstat., Hoorn.] English summary.

There are 3 palms of the *Astrocaryum* group in the Dutch East Indies, of which the kernels are collected and exported to Holland. The oil is a good edible oil. The percentage composition of the expeller-process residue of one of these, boegroemakka, was as follows: dry matter 87.55 and on the dry matter crude protein 10.17, true protein 10.07, fat 9.14, N-free extract 57.40, crude fibre 19.95 and ash 3.34. Digestibility coefficients of the organic constituents, from data for 2 wethers, in the same order were: 52.7, 57.3, 92.3, 83.2 and 54.3. Assuming a value (*Wertigkeit*, Kellner) of 100 on analogy with ordinary palm kernel, the starch equivalent of 100 g. dry matter is 84.0 or of 100 g. press cake with 12.45 per cent. moisture 73.5. The cake contains much less protein than ordinary palm kernel.—I. Leitch.

4256

CHAPPEL, C. F., SIRNY, R. J., WHITEHAIR, C. K. and MACVICAR, R. Effect of mineral supplements on digestibility of a corncob ration by sheep. *J. Animal Sci.*, 1955, **14**, 153-159. [Dept. Animal Husb., Oklahoma Agric. Exp. Stat.]

Digestibility by sheep of a corncob ration which had a low total ash content but had adequate total digestible nutrients, protein, calcium, phosphorus and cobalt was not improved by addition of sodium, magnesium, potassium, copper, manganese, zinc and iron. Digestibility of organic matter and crude fibre of such a ration was significantly increased by the addition of natural alfalfa ash and also by synthetic alfalfa ash. These additions also improved appetite.—J. C. Gill.

HORN, L. H. (JR.), SNAPP, R. R. and GALL, L. S. The effect of antibiotics upon the digestion of feed nutrients by yearling steers, with bacteriological data. *J. Animal Sci.*, 1955, **14**, 243-248. [Dept. Animal Sci., Univ. Illinois, Urbana.]

A series of trials were made to find the effect of
Vol. 25, No. 3

penicillin, aureomycin or a mixture of antibiotics and sulphathalidine on digestibility and rumen efficiency in year-old steers. The mixture of antibiotics given 9 days before the collection for estimation of digestibility increased the apparent digestibility of all the constituents of the feed. The effect of small doses of penicillin, 32 and 100 mg., was variable. Aureomycin at all levels, 32 to 100 mg., and penicillin at high levels, 400 and 800 mg., depressed the digestibility of protein and crude fibre. N retention was decreased equally by penicillin and aureomycin. The high doses of penicillin and all doses of aureomycin gave rise to a rumen flora unsuited to the digestion of fibre.

FROST, D. V., OVERBY, L. R. and SPREUTH, H. C. Arsenicals in feeds. Studies with arsanilic acid and related compounds. *J. Agric. Food Chem.*, 1955, **3**, 235-243. [Abbott Labs., N. Chicago, Ill.]

A review.

4262

LINTZEL, W. Probleme der Eiweissqualität im Erhaltung- und Leistungsfutter beim Pflanzenfresser und beim Fleischnfresser. [Protein quality in maintenance and production rations for herbivores and carnivores.] *Arch. Tierernähr.*, 1954, No. 5, Beihefte, 127-134. [Biochem. Lab. Prof. W. Lintzel, Krefeld.]

The argument is elaborated that protein metabolism in the plant-eater is a one-phase process, in the flesh-eater biphasic, i.e., that in the former the supply of protein is continuous, especially in the ruminant, and amino-acids go straight to the product; in the latter, deposit protein is first built and then is later used for production. From this it follows that the type of protein supplied is not important for maintenance in the plant-eater; proteins low in lysine, such as that of cereals and potatoes, are of full value. On the other hand, for production all animals require protein rich in all the essential amino-acids, especially lysine.

I. Leitch.

4263

HENNAUX, L. and LÉCOMTE, R. L'épeautre en alimentation animale. [Value of spelt in animal nutrition.] *Bull. Inst. agronom. Gembloux*, 1954, 22, No. 3/4, 232-234. [Stat. Recherches Zootech., Gembloux.]

Reasons for the superiority of spelt, a grain allied to wheat, over other cereals for the feeding of breeding livestock are unknown. A complete analysis, including proximate principles, minerals and vitamins (carotene, tocopherol and vitamin D) was made of spelt and other grains but only for vitamin D was a significant difference found. By biological estimation with rats, spelt was found to contain from 203.7 to 340.7 I.U. per kg. as compared with 33.2 I.U. for oats, 66.5 I.U. for winter barley and nil for wheat. The amino-acid contents are being investigated.—J. S. Thomson.

4264

WOODMAN, H. E. Rations for livestock. Minist. Agric. and Fish. Bull. No. 48, 1954, 13th ed., pp. iv + 150. H.M.S.O., London. Price 4s. 6d. net.

The new edition of this popular bulletin appears in its familiar form with all the information expected. There is an additional section on the use of antibiotics for fattening pigs, their advantages and limitations, and it is stressed that the last word has not yet been said on this matter. Another new section gives a general description of the American system of rearing baby pigs on artificial diets in brooders. The protein requirements of pigs are discussed with modifications based on recent investigations at Cambridge showing that high levels of vegetable protein may be as good as the normal levels of animal protein. In the section on calf rearing the findings of the Hannah Dairy Research Institute are described, embodying a warning about the risk that even low levels of cod liver oil may cause muscular dystrophy.

4266

WHITING, F. The feeding value of damaged grain. *Exp. Farms Serv., Dept. Agric., Ottawa*, Publ. No. 914, November 1954, pp. 13. [Exp. Stat., Lethbridge, Alta.]

A brief review is made of experiments on the uses of barley, wheat, oats and flax grains damaged by frost, mould, sprouting, rust, smut, ergot or fire, for stockfeeding. Though of lower feeding value than undamaged grains, they can usually be

given safely to all classes of stock. Exceptions which are harmful are ergot-infested grains of all cereals and frozen flax. Some types of mould may also be harmful, especially to horses.—T. D. Bell.

4267

FARINAS, E. C. *Ipil-ipil*, the "alfalfa" of the tropics. Its establishment, culture and utilization as a fodder and pasture crop. *Philippine J. Animal Indust.*, 1951, 12, 64-84. [Bur. Animal Indust.]

Ipil-ipil (*Leucaena glauca*) is a leguminous shrub occurring naturally in the Philippines. It provides good fodder with a high protein content, superior to alfalfa. It readily lends itself to cultivation. It can replace other roughages for ruminants, but the presence of a toxic substance, mimosine, makes it unsuitable for single-stomached animals. *Ipil-ipil* meal can be included up to 10 per cent. in rations for poultry. The plant, its habits, composition, cultivation and use are described.

JUCKER, H. Möglichkeiten zur Verbesserung der betriebseigenen Futterbasis. [Possibilities of improving homegrown fodder.] *Die Grüne*, 1954, 2, No. 14, pp. 18. [Inst. Haustiernährung, Eidg. Tech. Hochschule, Zürich.]

The first condition for productive and economic winter feeding of cattle is strict limitation to homegrown fodder. On this basis the improvement of homegrown fodder is urgently required. The effects of time of cutting and method of conservation on composition of pasture, satiety value, palatability, carotene content and feeding value, and the costs of different methods of conservation, are summarised in table and diagram. Examples are given of production rations for cows giving from 5 to 30 kg. milk daily.—I. Leitch.

4269

MYERS, K. H. and PASTO, J. K. Grassland in organization of dairy farms in northeastern Pennsylvania. *Pennsylvania Agric. Exp. Stat. Bull.* No. 583, September, 1954, pp. 25.

A survey of 304 representative farms in Northeast Pennsylvania was made. They were dairy farms with some permanent pasture, and some of the crop area under grass. Hay on all farms and grass or maize silage on some farms were used. Some maize and small grains were cropped, usually for stock feed.

The topography, climate and soil are very well suited to grassland, but few of the farms approached the desirable standard, and many pastures were in poor condition. Improvement of yield and quality, and in some cases greater areas, of grassland are advocated.—T. D. Bell.

BARRERO GONZÁLEZ, A. Modificación del valor alimenticio de la paja. [Improving the feeding value of straw.] *An. Inst. Invest. Vet., Madrid*, 1953, 5, 133-135. English and German summaries.

4271

ZORN, W. Antibiotica und züchterische Selektion. [Antibiotics and selection for breeding.] *Züchtungskunde*, 1955, 26, 257-264.

Aims in selecting stock for breeding will be to increase production by improving health, fertility, rate of growth and efficiency of use of feed. Antibiotics control disease, and so one means of distinguishing better stock is removed. A good criterion would be "so healthy that there is no reaction to antibiotics". Antibiotics may improve utilisation of feed, may appear to make a poor ration good and produce results in some areas that are not reproducible in others with different feeds. Their effects on production are small at the best. They have made it possible to rear pigs on artificial milk substitutes but none of these effects can replace selection to maintain and improve performance. So far, no effect of antibiotics on fertility has been claimed.—I. Leitch.

4272

Two pilot schemes to solve the overstocking problem in Tanganyika. *Trop. Agric., Trinidad*, 1955, 32, 30-37. [Dept. Vet. Serv., Tanganyika.]

In Tanganyika livestock are concentrated into relatively small areas because of the prevalence of tsetse fly and the scarcity of permanent water

supplies. To prevent further deterioration of the land some redistribution of stock is necessary. Large areas of natural grazing are available, but these might be ruined by the mismanagement of stockowners. A further problem is how to absorb and prevent the slaughter of the many immature animals which come on the market through culling and destocking. It has been shown that large-scale ranching and holding grounds not only are possible but can be profitable.—J. S. Thomson.

4273

COOLHAAS, C. Landbouwkundig onderzoek in Nieuw-Guinea. [Agricultural research in New Guinea.] *Landbouwk. Tijdschr.*, 1954 (Nieuw-Guinea No.), 30-38. [Landbouwhoges., Wageningen.] English summary.

In general, soils are of low fertility. Development must be based on the study and planned exploitation of "islands" of better soil. Possible crops are cocoa and rice, the rice to be grown on polders to be reclaimed.—I. Leitch.

4274

FARINAS, E. C. Better fodders and improved pastures in livestock production in the Philippines. *Philippine J. Animal Indust.*, 1951, 12, 45-60. [Bur. Animal Indust.]

In order to improve livestock and attain a greater degree of self-sufficiency in the Philippines with reduced imports of food and feedingstuffs it is necessary to improve pastures. The possibility of improving indigenous and importing other suitable fodder crops is discussed.—T. D. Bell.

4275

KALININ, V. I. Obezpechit' khoroschoe kormlenie loshadei kolkhozov. [The provision of good feeding for horses at collective farms.] *Konevodstvo*, 1954, 24, No. 10, 1-3.

Instructions are given for the maintenance of horses in winter and the necessity for laying in stocks of food, for providing warm stables and drinking water at stable temperature and for seeing that the food is properly prepared is emphasised. Oats and hay are no longer the only food for horses; working horses can be given up to 10 kg. potatoes and 15 kg. silage daily. Too much silage should not be given to brood mares lest it cause abortion. The rations of horses,

particularly working horses, should contain also succulent fodder and root crops. Potatoes could be either boiled or raw; root crops should be given raw.

On one collective farm the brood mares' daily ration consisted of 3 to 4 kg. oats, 10 kg. legume hay with timothy, 2 kg. oat straw and 2 to 3 kg. carrots. Salt licks were supplied. Part of the oat ration was germinated and given in this form from September to May. Green needles of firs and pines were a valuable source of vitamins. In spring the stallions were given increased amounts of concentrates in the ration, 300 to 500 g. germinated oats, and eggs before mating.

ROY, J. H. B., PALMER, J., SHILLAM, K. W. G., INGRAM, P. L. and WOOD, P. C. **The nutritive value of colostrum for the calf. 10. The relationship between the period of time that a calfhous has been occupied and the incidence of scouring and mortality in young calves.**

ROY, J. H. B., SHILLAM, K. W. G., PALMER, J. and INGRAM, P. L. **11. The effect of aureomycin on the performance of colostrum-deprived calves.** *Brit. J. Nutrition*, 1955, 9, 11-20; 94-103. [Nat. Inst. Res. Dairying, Univ. Reading.]

10. The results reported were extracted from experiments of randomised block design made during the winters 1949-50 to 1953-54 (see Absts. 4231, 5669, Vol. 21; 3014, Vol. 22 and 320, Vol. 24). In some of these experiments one calf in each block was deprived of colostrum. In each year the calfhous was disinfected at the end of winter and left empty during the summer months. During each winter it was filled with a succession of calves, each calf being kept there for 3 weeks. Data from 202 Shorthorn calves were available for statistical analysis. The incidence of scouring was lowest among calves occupying the calfhous immediately after the period of vacancy. Scouring increased with order of occupation. This effect was less noticeable among calves receiving whole milk than among those having a synthetic milk. The increase in scouring occurred irrespective of the amount of colostrum given to the calves and of the presence or absence of calves deprived of colostrum. Scouring was reduced after the calfhous was vacated for 47 days in mid-winter. Vacating the calfhous for 15 days had no effect. It is suggested that under ordinary farm conditions there may be a build-up of "infection" in calfhouses which are permanently occupied during the winter and that this may account for the known increase in scouring and mortality among calves in late winter.

11. Sixteen Ayrshire and 24 Shorthorn bull calves were used in an experiment of randomised block design with 4 treatments in each of 10 blocks. Three calves in each block were deprived of colostrum. One of these received no aureomycin, the remaining 2 received aureomycin, either 238 mg. daily from Aurolac for the first 5 days and 119 mg. for the subsequent 5 days; or 250 mg. crystalline aureomycin hydrochloride for the first 5 days followed by 125 mg. for the next 5 days. The fourth calf in each block received 6 pints of colostrum without aureomycin supplement. All

calves received a basal diet of whole milk. All of the calves receiving colostrum survived; 4 of the untreated calves deprived of colostrum died. One calf deprived of colostrum died on each of the 2 treatments in which aureomycin was given. Both aureomycin treatments significantly increased live-weight gain and reduced the incidence of scouring. Aureomycin treatment also reduced the incidence of high rectal temperature.—J. N. Aitken.

4277

ROBERTS, H. E., WORDEN, A. N. and EVANS, E. T. R. **Observations on some effects of colostrum deprivation in the calf.** *J. Comp. Pathol.*, 1954, 64, 283-305. [Dept. Animal Health, Univ. Coll. Wales, Aberystwyth.]

Calves deprived of colostrum showed a high incidence of scouring, and later joint-ill. Rectal temperatures were higher than normal, and showed a peak on the third and ninth day. Changes in the blood picture of normal calves and calves deprived of colostrum are described and discussed.

STAROSHEL'SKI, L. S. **Gigiena sokhraneniya i vyrashchevaniya telyat. [Method of rearing calves.]** *Veterinariya*, 1954, 31, No. 9, 21-25.

An account is given of the rearing of calves on collective farms. On one farm with a high standard of calf rearing, the calves eat hay at 5 to 7 days old and concentrates at 20 days. When they were a month old the ration was increased by the introduction of sliced carrots and beet, starting with 100 g. daily and rising to 2 kg. daily at 2 months. They were also given 10 to 15 g. salt each.

To prevent digestive disorders the calves were given infusions of hay, starting at 12 to 20 days, up to the age of 4 to 5 months; 50 litres of infusion were made from 7 to 9 kg. lucerne and vetch. The calves were given 0.5 litre at first and finally 5 to 8 litres. The average amount of feed per calf up to 6 months old was 380 kg. milk, 300 kg. hay, 200 kg. silage and root crops, and 180 kg. concentrates.—H. Scherbatoff.

4279

WILLIAMS, J. B. and JENSEN, C. **Dried rumen contents in calf milk replacements.** *Bi-m. Bull. N. Dakota Agric. Exp. Stat.*, 1955, 17, 91-94. [Dept. Dairy Husb.]

The inclusion of a preparation of dried rumen contents in a milk replacement formula had no effect on the growth rates of Holstein and Guernsey calves. Adding terramycin and vitamin B₁₂ to

N.A. and R., July 1955

the replacement formula also had no effect on growth rate. The growth rate of 2 calves receiving a replacement containing 20 per cent. of ground beet pulp was satisfactory, but there was considerable loss of hair over two-thirds of the body. The addition of soya bean lecithin to the experimental rations did not prevent the ingredients from settling out. The growth rate of a group of calves receiving whole milk was superior to that of calves on the experimental diets.—J. N. Aitken.

MEREGALLI, A. Contributo allo studio di un metodo pratico ed economico di allattamento di vitelle di razza lattifera. [A practical and economical method of feeding dairy calves.] *Ann. Sper. agrar.*, 1953, 7, 555-580. [Lab. Zootec., Florence.] English summary.

Four dairy heifer calves were successfully reared to 4 months of age with a great saving of milk. The method was to give colostrum and whole milk only for the first 3 weeks, and then gradually to decrease the milk at the rate of 1 litre a day and give concentrates and first quality hay to appetite. The concentrate mixture should contain about 18 to 22 per cent. protein, a quarter of this being of animal origin. The hay should be leafy alfalfa or seeds hay. No milk was given after 60 to 70 days. By this method about 600 litres of milk were saved per calf. The method is advocated only for dairy calves, though when the milk supplied by the dams of beef or dual purpose breeds is insufficient the same supplements might be used.—T. D. Bell.

SEN, K. C., PREMACHANDRA, B. N., DASTUR, N. N. and RANGASWAMY, M. C. Effect of iodinated casein on growth in calves. 2. Feeding iodinated casein at low levels. *Indian J. Dairy Sci.*, 1954, 7, 198-204. [Indian Dairy Res. Inst., Bangalore.]

For part 1, see Abst. 3866, Vol. 24.

The animals used were 15 female calves of the Gir, Sindhi and Ayrshire × Sindhi breeds. They were divided into 3 comparable groups of 5 animals. All groups received the same basal ration of 3 to 6 lb. of a mixture of lucerne and guinea grass, the higher amounts being given to the heavier animals. Ragi straw was given to appetite. A concentrate mixture was given at the rate of 1 lb. per 100 lb. liveweight to animals weighing less than 450 lb. and at the rate of 0.75 lb. to heavier animals. The crossbreds received an additional 0.25 lb. Group 1 was used as a control and received no iodinated casein. Calves in group 2 were given 1.25 g. per 100 lb. bodyweight for 20 weeks, after which it was withdrawn and the animals were kept under observation for a further 15 weeks. The third group received 0.75 g. per 100 lb. live-

weight for 20 weeks and the amount was then increased to 2 g. per 100 lb. liveweight for a further 10 weeks.

Growth in terms of liveweight gain was stimulated in both treated groups as compared with the controls. In the group which received 1.25 g. per 100 lb. liveweight the accelerated growth was maintained even after treatment stopped. When the amount given to group 3 was increased from 0.75 to 2 g. per 100 lb. liveweight the liveweight gain was reduced from 0.90 to 0.41 lb. daily.

KEHAR, N. D. Effect of feeding alkali-treated cereal straws on the growth of young cattle. *Indian J. Vet. Sci.*, 1954, 24, 189-216. [Div. Animal Nutrit., Indian Vet. Res. Inst., Izatnagar.]

Field experiments were made at 4 centres to compare untreated and alkali-treated straws for cattle feeding. Rice straw was used at 2 of the centres and wheat straw at the other 2. The straw was treated by soaking in caustic soda solution and then washing. Apart from the treatment of the straw for the experimental animals, management at each centre was not changed from the normal. Only at one of the centres was the level of nutrition up to the standards of Morrison.

The treated straw produced greater and quicker liveweight gains than the untreated. This effect was greater in the less well nourished cattle. The possible advantages and the economics of alkali treatment under Indian conditions are discussed.—T. D. Bell.

4283

GAUNYA, W. S., MOCHRIE, R. D., JOHNSON, R. E. and DEMBICZAK, C. M. Effects of adding small quantities of aureomycin (Aurofac) to the starter of calves. *J. Dairy Sci.*, 1955, 38, 1-5. [Dept. Animal Indust., Univ. Connecticut, Storrs.]

In a randomised block experiment with 24 calves the feeding of a calf starter supplemented with 4.5 or 9.0 mg. aureomycin per lb. had no effect on growth rates as compared with controls on a similar starter without aureomycin. The experiment was continued for 91 days. The efficiency of gain of the calves receiving the higher level of aureomycin supplement was greater during the first 49 days, but there was no difference between treated and untreated calves at the end of 91 days. Aureomycin did not reduce the incidence of scouring.—J. N. Aitken.

4284

LAMBERT, M. R., JACOBSON, N. L., ALLEN, R. S. and BELL, M. R. The relation of growth, feed

consumption, and certain blood constituents to changes in the dietary of young dairy calves. *J. Dairy Sci.*, 1955, 38, 6-12. [Dept. Animal Husb., Iowa Agric. Exp. Stat., Ames.]

Six calf starters were given, respectively, to 6 groups of 9 calves each during an experimental period of 116 days. The starters varied from simple to relatively complex mixtures. The ingredients were chosen from the following: ground maize, crushed oats, soya bean oilmeal, steamed bonemeal, salt, dried whey product, maize molasses product, wheat bran, linseed oilmeal, molasses and dehydrated alfalfa meal. The calves received whole milk for the first 7 weeks. The amount of starter was limited to 4 lb. per calf daily. Hay was given to appetite. Feed consumption and bodyweight were recorded. Samples of venous blood were analysed for reducing sugar, fat, vitamin A and carotenoids.

There was no significant difference between the groups in any of the characters studied. When the blood data of all groups were combined it was found that under the experimental conditions plasma fat values were closely correlated with dietary fat intake. The values reached a peak after the fourth week and were lowest at 9 weeks of age. Plasma carotenoids decreased during the initial 3 weeks but increased subsequently. Blood plasma vitamin A decreased during the last 3 weeks of the milk feeding period. After the withdrawal of milk there was a consistent increase in vitamin A. Blood glucose values declined during the first 6 weeks and remained relatively constant thereafter.—J. N. Aitken.

4285

KING, J. W. B. and DONALD, H. P. A study of variation in twin cattle. 3. Growth. *J. Dairy Res.*, 1955, 22, 1-9. [Agric. Res. Council. Animal Breeding Res. Organiz., Edinburgh.]

Increases in liveweight from birth to 19 months of age and in height at withers to 27 months of age of monozygotic twins, dizygotic twins and half-sisters from the same sire, all reared under the same conditions, were recorded, and the results were treated statistically. The variations between pairs in the 2 types of twins and the half-sisters were in the ratio of 1:6.8:10 for liveweight increase and there was a similar ratio for height at withers. It was calculated that unrelated pairs would show 20 times as much variation as monozygotic twins. The limitations of the present inquiry, and of the use of monozygous twins for experimental comparisons, are discussed.—T. D. Bell.

4286

NEWLANDER, J. A. and RIDDELL, W. H. Comparison of high-quality and low-quality hays for raising dairy calves. (Birth to 24 months

of age.) *Vermont Agric. Exp. Stat. Bull. No. 577*, November 1954, pp. 8. [Burlington, Vt.]

Dairy calves were raised from birth to 2 years of age. They received colostrum, whole milk for 5 weeks and skimmed milk for a further 4 weeks with the same grain ration, and had access to this and either good or poor quality hay from 2 weeks of age. Hay was given to appetite throughout the trial, and a maximum of 4 lb. grain in the first year and 2 lb. in the second year was allowed. The growth of the calves is considered in 6-month periods. Overall the calves getting good hay gained 10-18 per cent. more than the others, and this difference was seen in each separate period. In efficiency of feed conversion there was no difference between the groups.—T. D. Bell.

4287

VORSTER, T. H. The influence of certain environmental factors and breed differences on cattle production. *Rhodesia Agric. J.*, 1954, 51, 428-473. [Dept. Animal Husb., Matopos Res. Stat., Bulawayo.]

The natural conditions for cattle rearing in Southern Rhodesia are very poor. An extensive study was made to find the best type of stock for beef production under those conditions. Native and European cows were bred to native, Africander or Hereford bulls. All the animals in the investigation lived under the usual free range management of the area.

Birthweights and weaning weights of calves, the influence of dam and sire on them, their interactions and the influence of breed and parentage on growth rate and carcass characteristics were recorded and are discussed.

Birthweights were influenced most by the size of the dam, which was least in the native cows, and bull calves were heavier than heifer in each breed. The year and month of birth, and therefore the climate, also affected birthweights significantly.

Weaning weights were greater in the calves which were heavier at birth, and again the influence of the sire was negligible. The same was observed with weights at 4½ years of age, when they were slaughtered, and in the heifers at 3½ years of age, when they were bred.

Carcass weights and dressing percentages of the bullocks from European cows were greater; the highest grades were from Hereford sires. However, any small advantage of the progeny of Hereford was offset by the higher rate of mortality from birth to slaughter. Most of the deaths were from birth to weaning. Mortality was influenced by climatic conditions.

Taken as a whole, the amount of beef produced per cow bred was similar for all breed groups, since the higher survival rate of the native breeds offset their lower birthweight and growth rate. It

N.A. and R., July 1955

was not considered advantageous to introduce selected European cattle into the existing environmental conditions.—T. D. Bell.

4288

NELSON, A. B., FONTENOT, J. P., ROSS, O. B., MACVICAR, R. and DARLOW, A. E. **The value of 20-, 30-, and 40-percent protein supplements for wintering heifer calves.** *Oklahoma Agric. Exp. Stat. Bull.* No. B-437, November 1954, pp. 14. [Div. Agric., Oklahoma Agric. and Mech. Coll., Stillwater.]

Feeding trials were made with heifers on winter rations of hay or pasture. The trials were made in the same form in 4 consecutive years. Some of the heifers received hay and 1 lb. of 20, 30 or 40 per cent. protein supplements in drylot feeding (groups 1, 2 and 3). The rest grazed winter pasture and got 2 lb. of 20 or 40 per cent. protein supplement (groups 4 and 5) or 1 lb. of 20 or 40 per cent. protein supplement (groups 6 and 7). The average gains or losses of groups 1 to 7 were, respectively: -11, 34, 81, 15, 38, -26 and 15 lb. All heifers were grazed on summer pasture for the rest of the year after the winter feeding period. The average gains for the whole year were: 250, 273, 290, 276, 268, 250 and 266 lb. Among the animals fed in drylot, the winter gains were in direct proportion to the percentage protein in the supplement. On winter pasture, 2 lb. of 20 per cent. protein supplement was equal to 1 lb. of 40 per cent. protein. The subsequent gains on summer pasture were greatest in the heifers which had gained least during the winter.

Further trials to see what effect those treatments have on later life and reproduction are in progress.—T. D. Bell.

4289

LITTLE, C. J. **The palatability of hay crop silage treated with sodium bisulfite.** *Quart. Bull. Michigan Agric. Exp. Stat.*, 1954, 37, 119-121. [Dairy Dept., Upper Peninsula Exp. Stat., Chatham, Mich.]

In an experiment with heifers given a choice of untreated silage or silage treated with sodium bisulfite at the rate of 2 lb. per 500 lb. forage, more than half the daily intake of silage was of the treated kind.—J. S. Thomson.

4290

REID, J. T., TURK, K. L., HARDISON, W. A., MARTIN, C. M. and WOOLFOLK, P. G. **The adequacy of some pastures as the sole source of nutrients for growing cattle.** *J. Dairy Sci.*, 1955, 38, 20-28. [Dept. Animal Husb., Cornell Univ., Ithaca, N.Y.]

Groups of 2 or 3 steers, mostly Holsteins,

Vol. 25, No. 3

received herbage from 6 different pastures, either by grazing or by hand-feeding. Each pasture was studied at 3 to 5 stages of plant growth, between May and August, when composition, digestibility and amount of herbage consumed by the steers were estimated for 4 to 11 days. The hand-fed steers provided information needed to estimate composition and digestibility (see Abst. 3871, Vol. 24).

All 6 pastures were first-growth herbage, except in the last period or two when 5 of them were aftermaths. Non-legume pastures, especially those rich in brome grass, did not provide enough protein for growing cattle, by Morrison's standards, after the beginning of July. The pastures rich in legumes provided more than enough protein at all stages. Aftermath pastures, even the non-leguminous ones, met the minimum protein needs at the end of the experiment. It was concluded that under ordinary conditions of grazing or cutting most pastures supply enough protein, but with mature first-growth herbage a protein supplement may be needed.

The first-growth pastures became deficient in total digestible nutrients (TDN) earlier in the season and more often than they were deficient in protein, but aftermaths supplied enough TDN.

D. Duncan.

4291

KLOSTERMAN, E. W. and KUNKLE, L. E. **Acres yields of beef from corn and meadow crops.** *Ohio Agric. Exp. Stat. Res. Bull.* No. 753, January 1955, pp. 18. [Wooster, Ohio.]

The results of 4 years' feeding trials are reported. The relative values of maize silage (the whole plant, including the ear) with a protein supplement, with maize meal supplement, or alone, maize meal alone, hay crop silage alone or with maize meal supplement, and pasture were estimated. Pounds of beef produced per acre were determined from the area required to produce all the feeds given to the cattle. The average lb. beef produced per acre were: maize silage with soya bean oil meal 573; maize silage with soya bean oil meal and $\frac{1}{2}$ feed of maize meal (maize grain and cob) 508; maize meal and soya bean oil meal 438; hay crop silage and $\frac{1}{2}$ feed maize meal 430; pasture 368. When the market value of the cattle, based on grade, price per cwt. and dressing percentage, was considered the best overall returns were from cattle fattened on maize silage, $\frac{1}{2}$ feed of maize meal and protein supplement. Protein supplement was not required with hay silage.

Before a complete evaluation can be made a study of labour and equipment costs will be necessary, and the importance of grassland for the crop rotation and conservation of the soil must be considered.—T. D. Bell.

4292

NELSON, A. B., POPE, L. S., MACVICAR, R., DARLOW, A. E. and STEPHENS, D. F. Self-feeding salt and cottonseed meal to beef cattle. A summary of experiments on self-feeding winter supplements. *Oklahoma Agric. Exp. Stat. Bull.* No. B-440, November 1954, pp. 14. [Div. Agric., Oklahoma Agric. and Mech. Coll., Stillwater.]

Feeding trials were made with beef steers and pregnant beef cows over 3 years. The costs of cottonseed meal hand-fed and of a mixture of cottonseed meal and 25 per cent. salt self-fed to limit consumption were compared. In the self-feeding groups slightly more meal was eaten, and the cost of feed was slightly higher, but no account was taken of the cost of labour used in hand feeding on the one hand or of mixing and equipment on the other. No effect on weight changes or calving was found. Blood and milk of the self-fed cows were normal. It was concluded that as long as there is sufficient water and winter pasture, no danger arises from self-feeding a mixture of salt and cottonseed.—T. D. Bell.

4293

PAWSON, H. C. and INNES, P. Wintering store cattle. Cocker Park trial, 1953-54. *Agric., J. Minist. Agric. Engl.*, 1955, 61, 599-604. [King's Coll., Newcastle upon Tyne.]

Bullocks wintered indoors on hay, roots, oats and beans made greater gains than those wintered outdoors on hay, oats and beans, and also graded better at the end of the year. Heifers wintered did not gain as much as similarly managed bullocks.

In a trial comparing alfalfa and grass silages, the former produced inferior weight gains, probably because of lower intake owing to poor quality. Alfalfa and seeds hay were equal in feeding value for fattening bullocks, as was expected from the chemical analysis.—T. D. Bell.

4294

SHEPHERD, W. O. and DILLARD, E. U. Best grazing rates for beef production on cane range. *N. Carolina Agric. Exp. Stat. Bull.* No. 384, October 1953, pp. 23. [Raleigh, N.C.]

Beef cows and their calves were used to determine the best grazing rate for cane (*Arundinaria* sp.) range. The method was to let groups of animals graze equal areas for 7 months at different rates of stocking. The trials were made in 3 consecutive years. It was shown that the best results were obtained by using not more than 50 to 60 per cent. of the available forage in one grazing period. This allowed the greatest overall weight increases, and the stands of cane were maintained in vigorous condition.—T. D. Bell.

4295

VEZZANTI, V. and RAIMONDI, R. L'influenza della castrazione sullo sviluppo somatico e sui caratteri delle carni di vitelli piemontesi all'ingrasso. [The influence of castration on somatic growth and on the character of the meat of fattening Piedmontese calves.] *Riv. Zootec.*, 1954, 27, 341-347. [Ist. Zootec. Piemonte, Turin.]

Twelve bull calves of the Piedmontese breed, similar in age, weight and type, were reared under identical conditions, but 6 were castrated at 3 months of age and 6 were left entire. They were killed at 8 to 9 months of age.

The mean initial weights were identical, 72.3 kg. The mean final weight of steers was 316, that of bulls 340 kg. The mean daily increments were 975 and 1072 g. As both groups received the same amount of feed the coefficient of utilisation was better and the cost per kg. liveweight gain was less in the bulls than in the steers; the feed consumed per kg. liveweight gain was 9.86 per cent. less.

The differences in body measurements between the 2 groups are tabulated. Inspection favoured the steers, which received a commercial valuation on the hoof of L. 380 per kg., compared with L. 365 for the bulls. The killing-out percentages were 61.53 for steers, 61.02 for bulls, giving carcass weights of 198 and 214.5 kg. There was no difference in chemical analysis of meat samples. Beef from the steers was more acceptable in texture and flavour when cooked.

It is concluded that the use of entire bulls for production of baby beef in Piedmont could produce an appreciable increase in the annual output.—D. Duncan.

4296

BOHMAN, V. R. Compensatory growth of beef cattle: the effect of hay maturity. *J. Animal Sci.*, 1955, 14, 249-255. [Dept. Animal Husb., Univ. Nevada, Reno.]

Early- and late-cut hay as the only winter ration were compared for fattening beef cattle. When early-cut hay was given the cattle gained faster during the winter, but during the following summer, on pasture, those getting late-cut hay in the winter, with lower protein and less phosphorus, gained faster. At the end of the summer the difference between the groups was small but in favour of the animals fed on early-cut hay. When the experiment was continued through another year the animals getting the poorer hay in both winters had caught up with the others by the end of the second summer. There was no permanent stunting caused by the poor feeding in the first winter.—T. D. Bell.

4297

FERRARI, E. L'ingrassamento del bovino nelle stalle delle provincie lombarde. [Fattening of cattle indoors in the provinces of Lombardy.] *Riv. Zootec.*, 1954, 27, 356-357.

Methods of fattening dairy cows at the end of their productive life, and calves, are discussed.

D. Duncan.

4298

SEIDLER, S. Opas bydla młodocianego wybrakowanego na wywarze kiszonym ziemniaczanym i ziemniaczano-cykoriowym. [The use of distillery potato slop silage and chicory-potato slop silage for fattening young cattle.] *Rocz. Nauk rol.* [B], 1954, 68, 235-252. Russian and English summaries.

The trial was made on 24 Friesian bullocks aged 1 to 2½ years in 4 groups: (1) chicory and potato slop silage with concentrates throughout the period; (2) potato slop silage with concentrates throughout; (3) potato slop silage and concentrates after 43 days; (4) potato slop silage and concentrates after 71 days. Hay, straw and dehydrated sugar beet pulp were given to all groups.

All groups showed good weight gains, and feed utilisation was also good. There was little difference between groups in carcass quality at slaughter. By introducing the concentrates only after 71 days 124 kg. concentrates were saved, replaced by 473 kg. slop silage and 93 kg. sugar beet pulp. (From summary.)—J. S. Thomson.

4299

MARTIN, C. M., BRANNON, W. F. and REID, J. T. Relationship of size of growing cattle to pasture intake and its use as an index of palatability. *J. Dairy Sci.*, 1955, 38, 181-185. [Dept. Animal Husb., Cornell Univ., Ithaca, N.Y.]

Investigations with growing dairy and beef steers showed a significant correlation between the amount of dry matter eaten when grazing and the bodyweight of the animal. By using this correlation for adjustment of dry matter intake it would be possible to estimate the palatability of the pasture. Further studies with heavier, and mature, animals to examine this suggestion are contemplated.—T. D. Bell.

4300

McDOWELL, R. E., LEE, D. H. K., McMULLAN, H. W., FOERMAN, M. H. and SWETT, W. W. Body weights, body measurements, and surface area of Jersey and Sindhi-Jersey (F₁) crossbred females. *J. Dairy Sci.*, 1954, 37, 1420-1428. [Dairy Husb. Res. Branch, Agric. Res. Serv., U.S. Dept. Agric., Beltsville, Md.]

Bodyweight at all ages from birth, and during the first 3 lactations, body measurements at 6, 12

and 18 months of age and during the first lactation, and surface areas of mature animals were compared in pure Jersey cows and their Sindhi × Jersey daughters.

Bodyweights at all ages were greater in the crossbreds, and the difference was more pronounced from birth to 15 months. At the earlier ages the crossbreds were taller with greater body width and depth, but shorter bodies. The differences lessened with increasing age, and in some cases were reversed at 18 months.

There was no difference between breeds in the ratio of surface area to bodyweight or to the two-thirds power of bodyweight.—T. D. Bell.

4301

CAREROLL, F. D., ROLLINS, W. C. and ITTNER, N. R. Brahman-Hereford crossbreds and Herefords—gains, carcass yields and carcass differences. *J. Animal Sci.*, 1955, 14, 218-223. [Univ. California, Davis.]

When fattened in feedlot from autumn to spring, Herefords made significantly greater gains and were more efficient than Brahman × Hereford crosses. The dressing percentage of the crossbred was higher. There was little difference in the value of the cuts from the carcasses of the breeds; the crossbred had more bone but less fat. When percentage bone was estimated by complete de-boning and by consideration of the eleventh and twelfth ribs, there was a significant difference between the methods, but this was the same for the pure-bred and the crossbreds, and the latter method was sufficient for breed comparisons. Herefords graded higher than Brahman × Herefords, because they carried more fat and were better finished. There was a similar difference between heifers and steers. The heifers gained more slowly than steers but were mature at an earlier age, and carried more finish when fattened for the same time. Their carcasses had less forequarter and more flank and loin.—T. D. Bell.

4302

KIDWELL, J. F. A study of the relation between body conformation and carcass quality in fat calves. *J. Animal Sci.*, 1955, 14, 233-242. [Dept. Animal Husb., Univ. Nevada, Reno.]

The relation between body measurements and slaughter grade, carcass grade and dressing percentage was ascertained from data from 64 Hereford steer calves varying in age from 10 to 18 months. Heart girth was highly correlated with bodyweight; it was also closely associated with all other measurements except round (distance from patella to patella parallel to the ground), and with carcass grade. It was concluded that heart girth provides a more suitable measure of total size than weight for studies of growth. The most

important measures influencing carcase quality were chest width and the ratios height at withers : heart girth and length : heart girth.—J. N. Aitken.

WOODWARD, R. R., QUESENBERRY, J. R., CLARK, R. T., SHELBY, C. E. and HANKINS, O. G. Relationships between preslaughter and post-slaughter evaluations of beef cattle. *U.S. Dept. Agric. Circular No. 945*, May 1954, pp. 24. [Animal and Poultry Husb. Res. Branch, Agric. Res. Serv.]

Records of the growth and carcasses, including grading at slaughter, and efficiency of feed conversion, of 635 Hereford steers were collected from 1942 to 1951, and the relations between them were computed and all are presented in tables. All the steers were uniformly treated, and slaughtered after 252 days.

Birthweight was correlated with growth rate and carcase grade, more closely with the former. Weaning weight was not so closely related to growth rate, and was negatively correlated with efficiency of feed conversion. Efficiency of feed conversion was negatively correlated with dressing percentage but not correlated with any other carcase measurements. Long-bodied steers produced as desirable carcasses as the compact type. Grading before slaughter did not give a good estimate of dressing percentage.—T. D. Bell.

4304

CLEGG, M. T., ALBAUGH, R., STRONG, H. and COLE, H. H. The use of stilbestrol in fattening cattle. *California Agric. Exp. Stat. Circular No. 441*, October, 1954, pp. 16. [Div. Agric. Sci., Univ. California.]

A number of trials involving 599 cattle in all were made. The results showed that faster gains were made by cattle treated with stilboestrol, and carcase grades were almost as good as in untreated cattle. The treated animals ate more, but the efficiency of feed conversion was much greater, with higher financial returns. Heifers did not show sufficient improvement to make the treatment worth while. The stilboestrol was implanted subcutaneously in 5-mg. tablets, 60 mg. in one dose giving maximum effect. Implantation was in the neck in some trials, but later in the ear to ensure that there was no contamination of the edible portions, and this site proved just as efficient. Other effects of stilboestrol on the cattle, such as mammary development, which had subsided by slaughter time, and the raising of the tail, are discussed.—T. D. Bell.

BRÜGGEMANN, J. and DREPPER, K. Stoffwechseluntersuchungen an jungen Rinden. 1. Über den Stoffwechsel von Rohwasser, Trockensubstanz, Rohasche, organischer Substanz, Rohprotein, Rohfett, Rohfaser und der stickstofffreien Extraktstoffe. [Metabolism studies on young cattle. 1. Metabolism of moisture, dry matter, ash, organic matter, crude protein, crude fat, crude fibre and N-free extract.] *Arch. Tierernährung*, 1954, No. 5, Beihefte, 210-215. [Inst. Physiol., Univ. Munich.]

The investigation was undertaken to show whether there was a seasonal difference in metabolism in young cattle which might explain the occurrence of Lecksucht in winter in the district (Upper Bavaria), especially in moor areas. The farm on which the study was made lies partly on high moor, partly on moraine. Four young cattle were used, healthy except for a tendency to lick objects within reach more than normal young animals do. Two were thin. They were given weighed winter rations in cement stalls for 10 days during which faeces and urine were collected, and, after 26 days on grass, cut grass only for 10 days in stall. Data for intake and excretion of water, dry matter, ash, organic matter and the usual proximate constituents, and also for Ca, P, Mg, K, Na, Cl, S, Fe, Cu, Mn, Co, I and carotene are given.

Except for N there was little difference between metabolic behaviour on the winter rations of 16 kg. grass silage and 4 kg. hay and on the summer diet of grass to appetite. These provided, respectively, 2700 starch units (g. starch equivalent) with 470 g. digestible protein, and 5500 starch units with 690 g. digestible protein, but the N balance was negative on fresh grass. The balances of minerals and trace elements will be discussed in a later paper.

Natrium, Chlor und Schwefel bei gleichzeitiger Durchführung eines Gesamt-Nährstoffbilanzversuches. [Metabolism experiments on young cattle. 2. Metabolism of calcium, phosphorus, magnesium, potassium, sodium, chlorine and sulphur with simultaneous estimation of the balance of total nutrients.]

BRÜGGEMANN, J., DREPPER, K. and TIEWS, J. 3. Über den Stoffwechsel von Eisen, Kupfer, Mangan, Kobalt, Jod und Carotin bei gleichzeitiger Durchführung eines Gesamtnährstoffbilanzversuches. [3. Metabolism of iron, copper, manganese, cobalt, iodine and carotene with simultaneous estimation of the balance of total nutrients.] *Arch. Tierernährung*, 1954, 4, 219-230; 231-240. [Inst. Physiol. Tiere, Univ. Munich.]

2. The mineral balances discussed were obtained in the experiment described in the preceding Abst.

In the winter experiment the mean daily intakes and amounts retained, in g., were Ca 75.5 and 37.7, P 14.7 and 7.74, Mg 7.9 and 4.2, K 103 and 9.6, Na 3.8 and 2.4, Cl 34.0 and 10.0. In summer the corresponding amounts were Ca 63.0 and 23.2, P 25.0 and 16.0, Mg 7.3 and 1.15, K 112 and 7.2, Na 3.9 and 2.4, Cl 65.0 and 20.2. The apparently excessive retention of Ca and the wide Ca : P ratio, especially in winter, are discussed and it is stated that the optimum ratio is between 2 : 1 and 1 : 1. The licking disease might be related to the wide Ca : P ratio or equally to the wide K : Na ratio.

The balances of Cl and S showed no peculiarity. The blood contents of the minerals studied were estimated at intervals, and were always within normal limits.

3. The intakes of Fe, 860 mg. per head daily in the winter experiment and 770 mg. in the summer balance, were considered low. The Cu intakes, 18.5 and 18.6 mg., seemed low, but there was only one negative balance. There was excessive intake of Mn in winter, 2.2 g. daily, because a Mn fertiliser had been used in the preceding year, and 4 mg. daily was retained. The Co intakes were 170 and 196 µg. daily and might be insufficient.

Supplies of I and carotene were ample. Co and Cu were not estimated in the blood.

It is concluded that the licking disease in this region is probably caused by insufficient supply of several elements.—D. Duncan.

Über den Mineralstoffhaushalt und Mineralstoffbedarf von Milchkühen hoher Leistung unter den Futterverhältnissen des Rübenbaus nach Versuchen mit wechselnden Zulagen von Calcium und Phosphor. [3. Mineral metabolism and mineral requirements of high-yielding milk cows in fodder beet areas, from experiments with different supplements of calcium and phosphorus.]

BECKER, M., OSLAGE, W. and KARSTEN, G. 4. Menge, Verdaulichkeit und Bedeutung des Fettes und der essentiellen Fettsäuren im Futter bei Versuchen an Milchkühen hoher Leistung. [4. Quantity, digestibility and importance of fat and essential fatty acids in feed, from experiments with high-yielding milk cows.] *Arch. Tierernährung*, 1955, 4, 265-281; 282-292. [Inst. Tierernährung, Forschungsanst. Landwirtschaft., Brunswick, Völknerode.]

For earlier parts see Absts. 1619, Vol. 22; 3649, Vol. 23.

3. Ca and P balances were studied for eight 10-day periods in 3 cows at different stages of lactation and for 3 periods in dry pregnant cows. All were fed on ensiled beet tops, a little alfalfa hay, relatively large amounts of dried beet pulp, and concentrates consisting of wheat bran, soya bean meal and groundnut meal, according to milk yield. Even without added minerals the rations were rich in Ca and P. It was considered that the Ca requirement was high because all 3 bulky foods contained much oxalic acid. The negative Ca balances in cows receiving from 175 to 217 g. Ca daily and giving from 16.6 to 27.9 kg. milk were ascribed to interference of oxalic acid and other substances with Ca absorption. Retention of Ca occurred in one cow in 2 periods, after 121 and 169 days of lactation and with a yield of 24 kg. daily, when she received 256 and 261 g. Ca daily. The dry cows all retained Ca, from intakes of 94 to 113 g. P balances were all positive from intakes of 45.5 to 88.8 g. daily, but one cow had a negative balance in the second half of lactation from an intake of 43.5 g.

Supplements of calcium carbonate and phosphate are recommended for dairy cows.

4. In 4 similar experiments with cows on the rations described in the preceding Abst. fat balances were studied. Much of the faecal lipid was of endogenous origin, and it was considered that balances of essential fatty acids were of more value than conventional fat balances.

The bulk fodders, especially the silage, contributed at least as much as the concentrates to the supply of essential fatty acids. Bran at the rate of 2 kg. daily contributed some 40 per cent. of the

essential fatty acids for milk fat; extracted oil-meal with 1 or 2 per cent. fat contributed only 5 to 8 per cent.

The relation of the food fatty acids, especially linoleic acid, to milk fat production is discussed.

D. Duncan.

BECKER, R. B., ARNOLD, P. T. D., KIRK, W. G., DAVIS, G. K. and KIDDER, R. W. **Minerals for dairy and beef cattle. 1. Minerals for dairy cattle. 2. Mineral consumption by cattle on Florida ranges. 3. Relation of copper and molybdenum to cattle nutrition. 4. Recommended mineral mixtures.** *Univ. Florida Agric. Exp. Stat. Bull.* No. 513, February 1953, pp. 51. [Gainesville, Fla.]

There is a brief general discussion of the mineral requirements of livestock and their sources. Trials are reported showing the average monthly intakes of salt, bonemeal, phosphates and an iron, copper and cobalt mixture placed in boxes to which dairy cattle had free access. The effect of Ca and P deficiency on bone strength and milk production was demonstrated, and the choice of the different mineral supplements of cattle under different grazing and feeding conditions was investigated. It is recommended that minerals should be mixed with the feed, and that access to boxes containing salt, bonemeal or a salt and phosphate mixture, and an iron, copper and cobalt mixture be allowed. Where there is a likelihood or signs of Ca deficiency marble dust is a palatable, safe and cheap supplement.

Beef cattle on range, even when receiving supplementary feeds, ate mineral supplements from boxes, and chemical analyses of forage showed that some were deficient in P.

Copper and molybdenum in the nutrition of cattle are discussed, and signs of copper deficiency are described and illustrated. Suitable mineral mixtures for general use, and their preparation, are described.—T. D. Bell.

VENKATAPPAIAH, D. and BASU, K. P. **Non-protein nitrogenous constituents of milk. 2. Effect of feeding high and low protein rations to cows and of putting the cows to work.** *Indian J. Dairy Sci.*, 1954, 7, 213-218. [Indian Dairy Res. Inst., Bangalore.]

Normal, high- and low-protein concentrate mixtures were given in that order in 3 successive 14-day periods to 6 Sindhi cows, at the rate of 1 lb. per 2.5 lb. milk produced. A basal ration of guinea grass 40, ragi straw 5, groundnut cake 1 and gram husk 2 lb. was given throughout. The nutritive ratios of the 3 rations were, respectively, 1:6.7; 1:4.7 and 1:7.8. Total N, protein N and

N.P.N. were estimated on milk samples at intervals of 5 days.

N.P.N. as a percentage of total N in the milk of cows on the normal-, high- and low-protein mixtures was 5.14, 7.06 and 4.70. Total N.P.N., urea N and amino-acid N increased when the change was made from normal to high protein and decreased on the low-protein ration.

To study the effect of work on total N and N.P.N. of milk 2 groups of 7 Sindhi cows were used. One group was put to work for 4½ hr. daily. Each cow received a basal ration of ragi straw 6, hariali hay 2 and grass 28 lb. and a concentrate mixture at the rate of 1 lb. per 2.5 lb. milk produced. Working cows were given an extra 2 lb. of the concentrate mixture to meet their extra energy requirement. The difference between the total N and N.P.N. constituents of the milk of the 2 groups was not significant.—J. N. Aitken.

WITT, M. **Einfluss einer stark überhöhten Eiweissgabe auf die Milchmenge und den Fettgehalt der Milch bei Kühen. [Effect of excess protein on milk yield and fat content of milk in cows.]** *Arch. Tierernährung*, 1954, No. 5, Beihefte, 166-181. [Max Planck Inst. Tierzucht, Mariensee, Trenthorst.]

The transition from stall to pasture is usually followed by a fall in the fat yield of cows; the changes are many and their effects have not been separately analysed. Here, the effect of a sudden increase of protein in the ration was tested. There were 34 cows in all, with an average daily yield of about 20 kg. milk with 3.9 per cent. fat. They were in 3 sets of paired groups of which 1 group had the high-protein ration between 2 periods on the normal ration and the other group had 2 high-protein periods with a normal between. The normal ration was of hay, beet leaf silage, fodder beet, dried beet slices and Troblako, with a concentrate mixture of barley meal, oatmeal, wheat bran, soya bean meal and groundnut meal. This was abruptly changed to one of soya and groundnut only. The components were analysed and their feeding values were computed with conventional coefficients of digestibility. [There is no statement about the fat content of the oilmeals used.]

On the average, milk yield rose by 2.5 per cent. and fat fell by 0.128 per cent., both statistically significant results. [We are unable to reconcile these general conclusions with the detailed group data presented.]—I. Leitch.

4314

FRENS, A. M. **Die Fettversorgung der Milchkühe. [The supply of fat for dairy cows.]** *Futtermittel und Fütterung*, 1953, No. 35, pp. 3.

N.A. and R., July 1955

Studies were made on groups of from 6 to 13 dairy cows. The control groups received low-fat rations for 126 days; the experimental groups received the same rations for at least 35 days and then the experimental rations for 56 days.

The low-fat rations contained extracted oilcakes; in the experimental rations unextracted linseed, groundnut and coconut meals were combined.

In the first experiment the cows received about 19 kg. good silage and 6.6 kg. grass hay which provided about 360 g. crude fat daily; 5 kg. concentrates provided another 420 g. crude fat for the low-fat and 523 g. for the high-fat group. The only difference found between the groups was a slightly higher fat content of the milk of the high-fat group.

In the second experiment the basal ration of hay, fodder beet and rye straw provided only 121 g. crude fat daily, and the low- and high-fat concentrates brought the total fat intakes to 144 and 288 g. The low-fat group ate more than the high-fat group and gained slightly in weight. The experiment was repeated with fat intakes of 218 and 356 g. The high-fat group produced more milk than the low-fat group, with a mean difference of 1.05 ± 0.19 kg. per cow daily. It is concluded that when the bulk ration is relatively rich in fat the fat content of the concentrates is without effect on production, but that with low-fat bulky feeds a total of about 4 per cent. fat in the concentrates is needed for maximum milk production. A combination of hay and silage can provide sufficient fatty acids to eliminate the need for high-fat concentrates. The 3 oilcakes used in the experiment may increase butterfat production even when milk output is maximum.—D. Duncan.

4315

BALCH, C. C., BALCH, D. A., BARTLETT, S., HOSKING, Z. D., JOHNSON, V. W., ROWLAND, S. J. and TURNER, J. *Studies of the secretion of milk of low fat content by cows on diets low in hay and high in concentrates. 5. The importance of the type of starch in the concentrates. J. Dairy Res.*, 1955, 22, 10-15. [Nat. Inst. Res. Dairying, Univ. Reading.]

For part 4 see Abst. 2900, Vol. 25.

Fifteen cows were used in an experiment lasting 13 weeks. In the preliminary and final control periods, of 3 and 4 weeks' duration, all cows received 16 lb. hay daily and a mixture of concentrates at about 4 lb. per 10 lb. milk. The mixture, in parts by weight, was of decorticated groundnut cake 3, weatings 7 and flaked maize 10. In the intervening experimental period of 6 weeks the ration of hay was reduced to 4 lb. daily and that of concentrates increased for all. Five cows got the original mixture but for the 10 others changes were made and, for 5 and 5, respectively,

maizemeal and ground dredge corn (oats and barley) completely replaced the flaked maize.

In the experimental period yields of milk and of fat were less for the group on flaked maize than for the others. In the last 2 weeks of the period adjusted mean fat percentage for the flaked maize group was 0.51 and 0.71 below the means for the maizemeal and dredge corn groups, respectively. There was no effect on the solids-not-fat in percentage or total yield.

It is concluded that, associated with the changes produced during the processing of flaked maize by rupture of the grains and partial dextrinisation of the starch, there may have been an effect on the bacterial metabolism in the reticulo-rumen which would account for the findings.—D. Harvey.

4316

SCHOORL, P. *The relation between the crude fibre content of food and the milk production. Netherlands J. Agric. Sci.*, 1955, 3, 35-39. [Vet. Fac. Dept. Nutrit. Sci., Univ. Indonesia, Bogor.]

A survey of 27 farms in Indonesia, with, in all, 840 cows showed that the average weight was 450 kg., the daily feed consumption 1.2 kg. digestible true protein, 9.2 kg. starch equivalent and 4.1 kg. crude fibre and the daily milk production 5.6 litres. The intake is about twice the amount needed and is discussed in relation to the high respiration rate reported in imported as well as in some native-born Friesian cows. The high intake of crude fibre, much of it in a highly indigestible form, is thought to be the direct cause of the low milk yield and, in a preliminary trial with 1 cow given reedy grass (*Pennisetum maximum*) in her first and young meadow grass in her second lactation, the yields were 1003 litres in 110 days and 1870 litres in 102 days, respectively. Climatic conditions favour the growing of meadow grass; with suitable manurial treatment, the author has obtained a yield in a year of 120,000 kg. per hectare [47.8 tons per acre].—D. Harvey.

4317

BAILEY, G. L., CLOUGH, P. A. and DODD, F. H. *The rate of secretion of milk and fat. J. Dairy Res.*, 1955, 22, 22-36. [Nat. Inst. Res. Dairying, Univ. Reading.]

The effects of residual milk on the yield and composition of the milk obtained at subsequent milkings and the rate of milk and fat secretion after residual milk effects had been eliminated were investigated with 5 cows. Rates of secretion were measured at milking intervals of 3, 6, 9, 12, 15 and 18 hr. Statistical analysis of the results showed that the yield of milk increased with the length and decreased with the square of the length of the milking interval and of the previous milking

interval. Butterfat yield increased with the length of the milking interval and the length of the preceding milking intervals and decreased with the square of the length of the milking interval. The effect of the preceding interval on milk and fat yields was directly due to residual milk effects and to changes in the metabolic rate of the udder. As the length of the milking interval increased the rates of milk and fat secretion decreased.

J. N. Aitken.

4318

DIJKSTRA, N. D. Vergelijkende voederproeven met kunstmatig gedroogd voorjaars en herfst-gras bij melkvee. [Comparative feeding trials on dairy cows with artificially dried spring and autumn grass.] *Versl. Landbouwk. Onderzoek.*, 1954, No. 60.1, pp. 42. English summary.

Analyses of and digestibility trials with spring and autumn grass from the same fields show little difference in value but the impression persists among farmers that spring grass is better. Two trials were made with dried grass, the first lot from an aerodrome and not of ideal quality, the second from one of the best research pastures. Full details are presented of composition and digestibility, by wethers, of the grass and of the progress of the trials.

There was no significant difference in either trial in yield or fat content of milk or in condition of the cows. In both, iodine number of butterfat was slightly higher with autumn grass, and in both autumn grass gave slightly more carotene, 10.3 and 9.2 I.U. as against 9.3 and 7.2, and more vitamin A, 16.3 and 13.9 I.U. as against 15.5 and 13.4 I.U. per g. butterfat.—I. Leitch.

4319

ELLENBERGER, H. B., NEWLANDER, J. A. and JONES, C. H. Effects of feeding different grades of hay and cod-liver oil concentrate to dairy cattle. 3. From 361 to 720 days of age. *Vermont Agric. Exp. Stat. Bull.* No. 576, May 1954, pp. 44. [Burlington, Vt.]

The trials already described in parts 1 and 2 (Absts. 326, Vol. 22; 1725, Vol. 24) were continued over the fifth to eighth 90-day-periods of the cow's life. The animals were those left from the preceding trials, in all 43 cattle representing 4 generations. There were 4 groups getting good or poor quality hay each without or with cod liver oil, 10 ml. daily mixed with the feed. All groups received the same meal ration, about 1.6 lb. per head daily, and succulents and silage, about 20 lb. daily in season. Feed intake and weight changes were noted and blood was analysed for Ca and inorganic P.

In all the periods, taken separately or together, there was very little difference between the

groups getting poor and good quality hay, and the only advantage of cod liver oil was a slight improvement in the groups getting poor quality hay. All animals got as much nutrient intake as is recommended by the lower limits of the Morrison and Eckles standards, and Ca and P intakes were well above National Research Council recommendations. The weight increases in all groups were average.—T. D. Bell.

4320

BATTAGLINI, A. Ricerche comparative sul valore nutritivo della crusca di frumento, sgrassata con solventi chimici, e della crusca integrale, impiegate nell'alimentazione delle vacche da latte. [Comparison of the nutritive value of wheat bran defatted with chemical solvents and of whole bran in the feeding of dairy cows.] *Ann. Sper. agrar.*, 1954, 8, 1141-1149. [Ist. Sper. Zootec., Rome.] English summary.

In a trial lasting 139 days, with 2 groups of dairy cows, chemically extracted and whole wheat bran as 60 per cent. of the concentrate ration were compared. There was no difference between the groups in milk yield, butterfat percentage, body-weight changes, regularity of the sexual cycle or fertility.—T. D. Bell.

4321

HUFFMAN, C. F. and DUNCAN, C. W. Corn silage as a source of the unidentified grain factor(s) needed for milk production. *Quart. Bull. Michigan Agric. Exp. Stat.*, 1954, 37, 23-26. [Dept. Dairy Chem.]

The effect on milk production of replacing part of the hay in an all-hay ration by maize silage, on an equal total digestible nutrient (T.D.N.) basis, was determined in 7 trials with 8 Holstein cows. The all-hay ration was given in the preliminary period preceding each trial in order to deplete the cows of the unidentified factor(s) in grain needed to balance the T.D.N. in roughage (Abst. 3036, Vol. 22).

Replacement of part of the hay resulted in a significant increase in the production of fat-corrected milk. The increase in milk production coincided with a fall in T.D.N. intake. The cows lost weight in the initial stages of silage feeding. It is concluded that an allowance should be made for the amount of grain in the maize silage when feeding cows for efficient milk production.

J. N. Aitken.

4322

DUNN, K. M., ELY, R. E., HUFFMAN, C. F. and DUNCAN, C. W. The value of snapped corn-ear silage and grainless corn silage (ears removed) for milk production. *Quart. Bull.*

N.A. and R., July 1955

Michigan Agric. Exp. Stat., 1954, **37**, 223-229.
[Dept. Dairy Chem.]

Silage was made from chopped maize ears and from the chopped stalks after the ears had been removed. Tables of the composition and digestibility of these silages and of clover hay, maize-meal and corn-and-cob meal are presented.

When maize ear silage was given to dairy cows to replace half the hay ration on an equivalent total digestible nutrient (T.D.N.) basis, the production of fat-corrected milk increased from 16.0 to 20.8 lb. daily. Corn-and-cob meal was then introduced on the same basis in place of the silage, and the higher level of production was maintained.

When 55 lb. grainless maize silage replaced 17.6 lb. clover hay there was a slight increase in T.D.N. intake, which was the probable cause of the slight increase in milk yield. The grainless silage was then replaced by 10.8 lb. maize-meal, and milk production increased from 14.6 to 16.9 daily.

The results seemed to confirm previous suggestions that there is an unidentified factor in maize grain necessary to balance a hay ration for milk production (Abst. 3036, Vol. 22).—T. D. Bell.

4323

DUNN, K. M., ELY, R. E., HUFFMAN, C. F. and DUNCAN, C. W. **The value of corn silage and recombined corn silage in respect to milk production.** *J. Dairy Sci.*, 1955, **38**, 58-64.
[Dept. Dairy Chem., Michigan State Coll., East Lansing.]

Maize silage and recombined maize silage were compared in 14 trials with 11 Holstein and 2 Brown Swiss cows. The recombined silage consisted of silage from maize from which the grain had been removed and made into corn-and-cob meal. This meal was then used to supplement the grainless silage in amounts equivalent to ordinary maize silage. It was concluded that the maize grain in maize silage was of the same value for milk production as maize grain given in the form of dry corn-and-cob meal.—J. N. Aitken.

4324

FRENS, A. M. **The effect of silage-feeding on the quality of the milk.** *European Grassland Conference, Paris*, June 1954, pp. 7.

Substitution of good quality silage for hay in a hay and concentrate ration increased the vitamin A content and yellow colour of butterfat, and improved the spreading quality of butter through an increase in iodine number. Silage taints in milk are discussed.—J. L. Corbett.

FEATHERSTONE, J., GRIFFITHS, T. W. and SHUTTLEWORTH, F. A. **Silage for beef and milk production.** *Agriculture, J. Minist. Agric. Engl.*,

Vol. 25, No. 3

1955, **61**, 474-478. [Nat. Agric. Advisory Serv., W. Midland Province.]

The objects of the 2 trials described were to obtain information on the performance of dairy cows and fattening bullocks given heavy rations of silage, to determine the feeding value in terms of starch and protein equivalents from the performance of the animals and to compare these values with those obtained from the chemical analysis of the silage.

In the fattening trial the silage contained 17.5 per cent. dry matter, which contained 16.6 per cent. crude protein. The trial was made over a period of 5 months with four 2-year-old Shorthorn steers. The average consumption of silage over the period was 80 lb. per head daily. During the last 13 weeks of the trial oats were given at the rate of 5 lb. per head daily. The bullocks gained on the average 1.8 lb. per head daily. At slaughter all animals achieved satisfactory grades. The starch equivalent derived from the performance of the animals was 11.1 compared with 9.3 estimated from the analysis of the silage.

In an 8-week trial with 14 Ayrshire cows milk production was sustained on the following ration: 60 lb. silage and 10 lb. oats for maintenance and the first 2 gal.; over 2 gal., 3 lb. dairy cake. During the trial the cows lost on the average 19 lb. weight. The starch equivalent and protein equivalent from analysis were 9.5 and 1.75 and from performance 8.1 and 1.71.

Both trials were costed and steers born, reared and fattened on the farm returned a satisfactory profit when their whole life period was taken into account. In the milking trial it was estimated that the milk was produced at an average cost of only 2.1 shillings per gal.—J. N. Aitken.

4326

RICHARDS, C. R. and COOK, B. M. **Lima bean silage for dairy cattle.** *J. Dairy Sci.*, 1955, **38**, 34-39. [Dept. Animal Poultry Indust., Univ. Delaware, Newark.]

Lima bean and maize silages were compared in the rations of 2 groups of 3 lactating Holstein cows. The experiments were made in 2 successive winters and were of single reversal design. Both silages were given at a rate of 30 lb. daily, with a concentrate mixture according to production and hay to appetite. Analysis of the silages showed that the lima bean silage had less dry matter and more crude protein than the maize silage. Lima bean silage was less palatable. When the bean silage was given more hay was consumed. There was no difference between the groups in the amount of milk produced. The digestibility of the bean silage was estimated in a digestion trial with 2 young Holstein bulls. The apparent digestibilities of the dry matter, crude protein, ether extract

and carbohydrates were, respectively, 53.3, 41.1, 43.2 and 60.2 per cent.—J. N. Aitken.

DAMMERS, J. Hebben rauwe en gestoomde aardappelen bij rundvee een specifieke werking op resp. de melkproductie en de vetaanzet? [*Have raw and steamed potatoes specific effects on milk production and fattening in cattle?*] *Versl. Landbouwk. Onderzoek.*, 1954, No. 60-6, pp. 27. English and French summaries.

There is a popular belief that raw potatoes increase milk yield of cows and steamed potatoes lay on fat. The belief was tested in experiments in each of 2 years with 2 groups of sterile cows fattened during their last lactation and with dairy cows in early lactation, a total of 72 cows. The experimental period was of 8 weeks. There was no effect on milk yield or weight gained by the sterile cows but raw potatoes raised and steamed potatoes reduced the fat content of milk by from 0.08 to 0.20 per cent.—I. Leitch.

ASHEFA, M. and MASON, I. L. Environmental and genetical effects on milk yield in Pakistani buffalo. *Empire J. Exp. Agric.*, 1954, 22, 161-175. [Dept. Anat., Punjab Coll. Animal Husb.]

The conditions and management of the government buffalo breeding farm, Bahadurnagar, is described. The records of 754 lactations of 338 buffalo cows on this farm between 1947 and 1951 were examined. The average age at first calving was 3 years 11 months, and calving was most frequent in the hot wet summer. The average interval between consecutive calvings was 487 days, but this had decreased from 614 days in 1947 to 385 days in 1951, owing to improved management. The average yield was 438 gal., less in summer than in winter calvings. The second calving gave a yield 11 per cent. greater than the first, and the third 8 per cent. greater than the second. The length of the dry period was reduced by the later improved management, but this did not affect the milk yield. The heritability of yield was low. Owing to lack of equipment milk fat was not estimated.—T. D. Bell.

ITTNER, N. R., GUILBERT, H. R. and CARROLL, F. D. Adaptation of beef and dairy cattle to

the irrigated desert. *California Agric. Exp. Stat. Bull.* No. 745, September 1954, pp. 36. [Div. Agric. Sci., Univ. California.]

There is an introductory discussion on the reaction of cattle to hot climates, and the climate of the area of California under investigation is described.

For the investigation on dairy cattle, Holsteins, Jerseys and Guernseys were used. The effects of environmental temperature on body temperature, respiration rate, milk yield and general behaviour were recorded. High environmental temperatures increased body temperature and respiration rate, and milk yield declined. The critical temperature was higher in Jerseys and Guernseys, and they were more heat-tolerant than Holsteins. The higher-yielding cows showed greater changes in body temperature and yield than the lower. Dry cows showed least reaction to heat. These reactions are related to the amount of feed eaten. When cows with 80 per cent. black and 80 per cent. white coats were kept in direct sunlight, the respiration of the dark cows was significantly faster than that of the light, and it was concluded that this was due to greater absorption of solar heat.

Feeding trials were made with beef breeds of Brahman, Braford, Hereford and Hereford × Shorthorn steers and heifers. As was expected, the steers in each breed gained faster and more efficiently than the heifers. Herefords gained best in feedlot, but Brafords on pasture. Over the whole feeding period Herefords, though slightly smaller in measurements, gave heavier final liveweights, but the higher dressing percentage of Brafords compensated for this at slaughter, and there was little difference between the breeds in efficiency. The Brahman and Hereford × Shorthorn breeds were not satisfactory. Natural or constructed shade in the area is important.

Trials with alfalfa, fescue, and some tropical grasses showed alfalfa the best, then fescue. The tropical grasses were not suitable.—T. D. Bell.

WEBER, F. Vergleichende klimatologische und physiologische Untersuchungen am Rind in einem Offenstall und in einem Stall konventioneller Bauart. [*Comparative climatological and physiological studies of cattle in an open stall and a stall of conventional structure.*] *Ztschr. Tierzücht. Züchtungsbiol.*, 1954, 64, 1-24. [Inst. Tierzucht, Eidg. Tech. Hochschule, Zürich.]

This experiment was designed for demonstration purposes and the stock in the open stall was a mixed group of 7 cows at different stages of lactation and 2 young animals, with which was matched a group in the closed stall. The stalls were planned to give the maximum "climatic" difference

N. A. and B., July 1955

possible in one building. Details are presented. Mean temperature in the open stall was on the average 5.4° C. and in the closed stall 12.8° C. above external temperature, with which both varied closely; but the humidity in the open stall was only 60 per cent. of that in the closed.

Milk and fat yields were compared by averaging the yields of comparable weeks in lactation for paired animals and totalling the results. In the open stall there was a total of 4824.6 kg. milk with 194.09 kg. fat, compared with 4898.5 kg. milk and 180.55 kg. fat in the closed stall. There was no significant difference, therefore, in the long-term yield, nor was there any in the day-to-day variation or the reaction to extremes of cold. The young animals showed no difference in weight gain. Pairs were fed on the same standard allowances so adjusted to milk yield that there was little left over and what there was, was weighed and deducted. Feed consumption for one comparable pair in starch equivalent was 6190 kg. in the open and 6139 kg. in the closed stall. There was a small and barely significant difference in the amount of water drunk, 10.9 kg. more for the whole group per week. For a rise of temperature of 1° C. (average for a week) animals in the open stall drank 6.3 litres more, daily, and in the closed stall 11.9 litres per group.—I. Leitch.

STOCKKLAUSNER, FR. Bericht über die Forschungen auf dem Gebiet der Höhengviehzucht von 1945 bis 1954. [Studies of the breeding of Highland (Germany) cattle from 1945 to 1954.] *Züchtungskunde*, 1955, 26, 237-257. [Weihenstephan.]

The mean length of life of this breed is about 9 to 12 years; the mean herd life about 7 years. The main reason for disposal is infertility, estimated at from 25 to 35 per cent. of disposals. The incidence is much higher in some families than in others. Mean age at first calving is about 33

months, the mean interval between calvings 13 months.

The 3 races, Spotted Mountain, Brown Mountain and Hinterwald, have similar milk yields, the first 2 with a maximum in the third lactation and the last in the sixth lactation. The Hinterwald is much more efficient than either of the others, requiring 22 per cent. less starch equivalent per kg. milk. Several studies of the feeding and production of different herds are quoted; some of these include studies of working cows.—I. Leitch.

TAYLOR, J. I., ROLLINSON, D. H. L. and HARKER, K. W. Studies in the habits of Zebu cattle. 2. Individual and group variation within a herd. *J. Agric. Sci.*, 1955, 45, 257-263. [Animal Health Res. Centre, Entebbe, Uganda.]

For part 1 see Abst. 5400, Vol. 24.

2. Observations were made of a herd of 10 cows during a total of 336 hr. in 2- and 3-day periods from September to February. The animals were moved to 3 different pastures. The times spent grazing and ruminating by each individual were noted. There was less than 10 per cent. difference between the longest and shortest times recorded for either grazing or ruminating on different days or paddocks. Between individuals most did not differ more than 5 per cent. in times spent on any one day, and the individual patterns were the same. It was concluded that in herd studies of behaviour at least 4 cows should be used for accuracy, and the accuracy will increase in proportion to the number of animals over that number.

RAGAB, M. T., ASKER, A. A. and HILMY, S. A. Milk yield in the Egyptian cow as affected by age, dry period and month of calving. *Indian J. Dairy Sci.*, 1954, 7, 171-177. [Dept. Animal Breeding, Fac. Agric., Univ. Cairo.]

The data comprised 520 lactations of 177 Egyptian cows collected over a period of 20 years. Only complete records of animals free from disease were used. The data were statistically analysed.

The average age at first calving was 34.3 months, range 20 to 44 months. There was no significant effect of age at first calving on milk yield. Maximum total milk yields were attained at the fifth and sixth lactations. No statistically significant effect of month of calving on milk yield was found. Animals which calved in November, however, generally showed the highest yields. The length of dry period declined with advancing age; its average length was 193 days. A negative and highly significant regression of length of preceding dry period on milk yield was obtained.

J. N. Aitken.

DAVEY, G. P. and ALEXANDER, G. I. **The accuracy of estimation of a dairy cow's production of milk and butterfat.** *Queensland J. Agric. Sci.*, 1954, **11**, 75-77. [Cattle Husb. Branch, Queensland Dept. Agric., Brisbane.]

Milk yield was estimated on the basis of weekly, fortnightly and monthly records of 89 Jersey cows, and the results were compared with the actual yield. Butterfat production and percentage of 53 cows estimated on weekly and monthly tests were compared with the actual values. The degree of accuracy was greatest in the most frequent sampling. For practical use, when only a few animals are involved, weekly samples would be necessary, but monthly tests might be sufficient when large numbers of animals are used.—T. D. Bell.

DODI, B. **La necessità di un controllo del potere oitocico di talune farine di pesce destinate all'alimentazione delle femmine gravide.** [The necessity for a test of the oxytocic value of some fishmeals destined for the feeding of pregnant females.] *Riv. Zootec.*, 1953, **23**, 43-45. [Ist. Zootec. Gen., Univ. Cattolica del Sacro Cuore, Milan.]

Extracts of poor quality fishmeal in alcohol, alkali or acid had an oxytocic effect on the uteri

of rats and guineapigs, causing rhythmic contractions. This was thought to be the reason for abortion which had been seen in a herd of cattle. The effect depended on the freshness of the fish and the speed at which it had been dried. A simple method of detecting oxytocic action with a myograph is described, and it is suggested that such a routine test of all fishmeal, especially when destined for breeding females, would be desirable.

HANSEN, K. **Afkomsprøver med tyre. 9. [Progeny testing with bulls. 9.] Forsøgslab. København Beretn.**, 1954, No. 276, pp. 230. English and German summaries.

In general heifers received in late pregnancy were not in good condition. Details are presented of the feeding plans before and after calving, winter and summer rations. Before calving the allowance was 4 feed units of roots, 1 feed unit as beet tops and 2 kg. concentrates. Winter rations after calving were of 1.5 feed unit swedes, 1 feed unit silage or beet tops, 2.5 kg. hay and beets and concentrates graded to milk yield. The rations are given also in terms of total feed units, g. digestible true protein and g. Ca and P. The scheme for allowance of concentrates during summer in accordance with milk yield and quality of pasture is shown.—I. Leitch.

HICKMAN, C. G. **A new era of dairy cattle breeding.** *Agric. Inst. Rev., Canada*, 1955, **10**, 11-12; 49. [Animal Husb. Div., Exp. Farms Serv., Ottawa.]

Artificial insemination has started a new era in the improvement of dairy cattle. For success a balance must be struck between the use of bulls already proved and of animals under test for future use. Progeny testing should embrace as wide a range of conditions as possible. A method for the selection of bulls is suggested and discussed. Apart from the general improvement of stock which is made possible by artificial insemination, there is an advantage to be gained by the elimination of hereditary abnormalities. The discovery that semen can be stored by refrigeration makes it easier to extend the use of artificial insemination.

BURRIS, M. J. and BAUGUS, C. A. **Milk consumption and growth of suckling lambs.** *J. Animal Sci.*, 1955, **14**, 186-191. [Univ. Arkansas.]

Daily milk consumption of 18 single lambs and

N.A. and R., July 1955

5 sets of twins was measured at weekly intervals from 1 week to 12 weeks of age. Lambs were weighed before and after each of 4 sucklings on the day of recording. Milk production was highest during the first 4 weeks, fell rapidly during the next 4 weeks and then declined slowly to weaning. A positive correlation was found between total milk production and weight of ewe ($r = 0.74$), birthweight of lambs ($r = 0.50$) and udder width at lambing ($r = 0.47$). Daily milk production of ewes suckling singles was very similar to that of ewes suckling twins. Average daily gain of lambs was highly correlated with milk consumption in the first 4 weeks. The correlation decreased rapidly and was not significant from 12 to 16 weeks. Total milk production and growth of lamb to 16 weeks were highly correlated ($r = 0.83$).

CATE, H. A., LEWIS, J. M., WEBB, R. J., MANSFIELD, M. E. and GARRIGUS, U. S. The effect of pelleting rations of varied quality on feed utilization by lambs. *J. Animal Sci.*, 1955, **14**, 137-142. [Univ. Illinois, Urbana.]

Rations of alfalfa and maize; timothy, maize, molasses and soya bean meal; and timothy and maize, each in either meal or pelleted form, were given to one of 6 groups of lambs. Rate of daily liveweight increase was significantly increased by pelleting both the timothy rations, and these rations pelleted were better than the higher quality alfalfa and maize ration as meal. Feed intake also was increased by pelleting the timothy rations, and on all 3 rations efficiency was better when the feed was pelleted, the improvement being greater the lower the quality of the ration. Higher carcass grades were obtained with pelleted timothy but not alfalfa rations, as compared with the corresponding meal. Before the feeding trial began all the lambs were vaccinated with *Clostridium perfringens* type D against enterotoxaemia; this did not affect liveweight gains. Mortality was low, only 5 out of the total of 307 lambs, and death was due to enterotoxaemia.—T. D. Bell.

4346

CLARKE, E. A. Early weaning of lambs on hill country. *N.Z. J. Agric.*, 1954, **89**, 471-476. [Dept. Agric., Animal Res. Stat., Ruakura.]

Two hundred Romney ewes were used in a trial in which half the ewe lambs were weaned at 12 weeks and the other half at 17 weeks. After the late weaning all the lambs were run together and no difference was found between weight gains or worm burdens of the groups. Small differences between groups in similar trials over the next 2 years appeared to be due to feed conditions, not to time of weaning. Pasture can be more efficiently utilised, weed control more effectively

achieved and shearing simplified by the practice of early weaning.—J. C. Gill.

4347

DAVIES, G. M. Wintering ewe lambs. Some Welsh trials. *Scot. Agric.*, 1954-55, **34**, 149-153. [Univ. Coll. N. Wales, Bangor.]

Groups of about 50 ewe lambs were away-wintered at 4 farms in the first year of the trial described, and 5 in the second and third years. Results showed that the less weight gained by the lambs during winter the greater the gain on the hill during the summer, but under the conditions of the trial a winter gain of at least 6 lb. was desirable. Poor wintering led to lower fertility in the first breeding season and was responsible for a drop of 1 lb. in fleece weight at first shearing when compared with good wintering.—J. C. Gill.

NOBLE, R. L., POPE, L. S. and GALLUP, W. D. Urea and methionine in fattening rations for lambs. *J. Animal Sci.*, 1955, **14**, 132-136. [Dept. Animal Husb., Oklahoma Agric. Exp. Stat., Stillwater.]

In 3 trials supplements of methionine, urea and soya bean meal to a basal ration for fattening lambs were compared. Neither methionine nor urea alone consistently raised daily liveweight gain, but in combination there was a small, though not statistically significant, increase. This may have been due to an improved ratio of N:S, which was reduced from 59:1 to 15:1. Lambs given a supplement of soya bean meal with or without methionine did best; the methionine gave no advantage. The basal ration had approximately 8.5 per cent. protein, and the supplements of urea or soya bean meal raised the protein equivalent to 11 per cent. The rations were all equal in total digestible nutrients. There was no difference between any of the groups in dressing percentage or carcass grade.—T. D. Bell.

4350

REPP, W. W., HALE, W. H., CHENG, E. W. and BURROUGHS, W. The influence of oral administration of non-protein nitrogen feeding compounds upon blood ammonia and urea levels in lambs. *J. Animal Sci.*, 1955, **14**, 118-131. [Iowa Agric. Exp. Stat., Ames.]

Toxicity to 30 lambs of urea, ammonium formate, ammonium acetate, ammonium propionate and propionamide given by mouth was investigated by

testing 350 blood samples for ammonia and urea N. Further tests on 15 lambs were made with ammonium succinate, formamide, biuret, glycine and guanidine carbonate. With the exception of the last, toxicity was associated with large increases in blood ammonia N, 1 mg. per 100 ml. blood being the critical level. Amounts of the first 4 compounds listed equivalent to 40 g. urea proved fatal. Non-significant increases in blood ammonia and urea N resulted from the other compounds.

J. C. Gill.

4351

ALBERT, W. W., GARRIGUS, U. S., FORBES, R. M. and HALE, W. H. Modified urea supplements with corn silage for wintering ewe lambs. *J. Animal Sci.*, 1955, 14, 143-152. [Dept. Animal Sci., Univ. Illinois, Urbana.]

Four groups of 23 western crossbred ewe lambs were given maize silage and soya bean oilmeal. In 3 groups two-thirds of the N of the soya bean was replaced by urea plus cerelose and in 2 groups elemental sulphur was added. Weight gains did not differ significantly between groups, but the wool yield of the urea and cerelose group was significantly less than the average yield of the other 3 groups. In a second trial with 36 lambs supplements to silage of cerelose and starch plus urea, and yellow maize plus urea, both with and without sulphur, were compared with soya bean meal. Lambs receiving the soya bean meal supplement made significantly greater gains than those on the modified urea supplements. Addition of sulphur to the urea supplements increased gains. Ground maize produced significantly greater gains than cerelose and starch.—J. C. Gill.

LUCIFERO, M. Contributo sperimentale allo studio della influenza degli ormoni estrogeni sull'ingrassamento degli agnelli. [Experimental contribution to the study of the influence of oestrogenic hormones on fattening in lambs.] *Riv. Zootec.*, 1954, 27, 358-363. [Centro Gen. Animale Cons. Naz. Ricerche, Ist. Zootec., Univ. Florence.]

The literature is briefly reviewed.

Experiments were made on 8 ram lambs of the Vicentina breed, a triple-purpose type. Four were twins, 2 were singles and the other 2 had female twins not used in the experiment. They were equally divided into 2 groups, those untreated and those which had a tablet of 12.5 mg. stilboestrol implanted subcutaneously. The experiment lasted 60 days, beginning when the lambs were 70 days old. They received hay and concentrates to appetite.

The mean weight increase was 11.18 kg. in controls and 12.89 kg. in treated lambs; the mean daily increments were 186 and 214 g. The total

feed intake was almost identical, but the treated animals ate rather more concentrates and less hay. Treated and untreated sheep ate, per kg. live-weight gain, 1.7 and 2.2 kg. hay, 3.1 and 3.5 kg. concentrates, 4.27 and 4.87 "forage units", 0.74 and 0.85 kg. protein; the former thus gave better utilisation.

The differences did not reach statistical significance, but experiments on a larger scale are planned.—D. Duncan.

4353

CLEGG, M. T., ALBAUGH, R., LUCAS, J. and WEIR, W. C. A comparison of the effect of stilboestrol on the growth response of lambs of different age and sex. *J. Animal Sci.*, 1955, 14, 178-185. [Dept. Animal Husb., Univ. California, Davis.]

Twelve trials were made, in which a total of 318 lambs were treated, with about the same number of untreated controls. The lambs were of both sexes, ranging in initial liveweight from 20 to 60 lb., and were treated by implanting 12 or 15 mg. stilboestrol in the ear, in all except one trial, in which there was a group implanted with 36 mg. The length of the trials ranged from 65 to 130 days. In some trials supplementary feed was given, in others all feed was supplied by pasture. In all trials treatment raised the rate of liveweight increase, with no difference between sexes, and there was no difference between the types of feeding or the age at which treatment was given. In the trial in which treatments with 12 and 36 mg. stilboestrol were compared there was no difference between these groups. The treated animals in this trial had heavier pituitaries and adrenals. There were only 3 cases of vaginal prolapse and one of rectal prolapse in all the trials.

CARENA, A. Influenza dell'alimentazione con gusci di semi di cacao su la produzione latte delle pecore e la fabbricazione della robiole. [Effect of cocoa pods on the milk production of ewes and on cheese making.] *Ann. Sper. agrar.*, 1954, 8, 1857-1879. [Ist. Zootec. Cascar. Piedmont, Turin.] English summary. Cocoa pods had a nutritive value two-thirds that of bran. They could form up to 30 per cent. of the ration of ewes. No alkaloid poisoning was observed, but milk yield was slightly reduced when the pods replaced bran. Cheese made from the milk of ewes fed on cocoa pods ripened more slowly than usual, but there was no other effect on the quality.—T. D. Bell.

4357

BIELIŃSKI, K., SZYFTER-ZIOŁECKA, A. and BIELIŃSKA, K. Opas skopów na kiszonych wysłodkach buraczanych. [Fattening of wethers on sugar beet pulp silage.] *Rocz. Nauk rol.* [B], 1954, 68, 217-233. [Inst. Zootech., ZD Kohna Wielka.] Russian and English summaries.

The addition of 0.5 kg. barley daily to a ration of sugar beet pulp silage, hay and straw for fattening wethers reduced the fattening period by 2 to 3 weeks but had an unfavourable effect on feed utilisation and cost of liveweight gain. The addition of the concentrate slightly improved carcass quality. Up to 8 lb. sugar beet pulp silage daily could be given without detriment to health. (From summary.)—J. S. Thomson.

4358

BLAKESLEE, L. H., HENNEMAN, H. A. and NELSON, R. H. A comparison of hay, hay-crop silage and corn silage for ewes during gestation. *Quart. Bull. Michigan Agric. Exp. Stat.*, 1954, 37, 72-80. [Dept. Animal Husb.]

Sixty-five and 60 ewes were used in 2 trials to compare different rations during pregnancy. Ewes fed on hay, and their lambs, made better gains than those on hay-crop silage, although the latter as the sole roughage, when supplemented with Ca and P, can produce good lambs. When the hay-crop silage was given with maize silage or dry roughage gains in ewes and lambs were better. For comparable results with other roughages hay-crop silage would require a grain supplement.—J. C. Gill.

BRITON, N. W. and PALTRIDGE, T. B. A study of liveweight increments in ewes and of carcass quality and maturity rates in lambs grown on sown pastures in south-eastern Queensland. *Queensland J. Agric. Sci.*, 1954, 11, 43-59. [Queensland Agric. High Sch. Coll., Lawes.]

Sown pastures of alfalfa, paspalum grass and alfalfa, paspalum grass, and paspalum grass and *Phaseolus lathyroides* were compared. The weight changes of dry ewes and ewes in lamb with singles and twins, and fattening lambs on these pastures, and the carrying capacity of the pastures, were observed.

Highest weight gains of all the ewes were recorded on the alfalfa pasture, but the rate of stocking was lower than on the grass pastures. Alfalfa and grass was the best, but was difficult to maintain.

The rate of liveweight increase and the quality of the carcasses of lambs was highest on alfalfa; alfalfa and grass gave almost as good results. The other pastures did not allow quick enough growth of the lambs. A close correlation was found between the age at maturity, and therefore the rate of growth, and the carcass quality.

SCHOLZE, F. Die Junglämmernast beim Leineschaf unter besonderer Berücksichtigung von Milchleistung und Futtermittelverwertung. [Fat lamb production in the Leine sheep with special reference to milk production and feed utilisation.] *Ztschr. Tierzücht. Züchtungsbiol.*, 1954, 64, 25-46. [Inst. Tierzücht, Univ. Göttingen.]

The Leine sheep is found mostly in the south part of Lower Saxony along the Leine River, and on the southwest slopes of the Harz Mountains. It was at one time almost a distinct breed but has recently been crossed with foreign breeds to improve mutton qualities.

Mutton is unpopular in Germany as soon as the sheep is so old that the fat has a tallowy taste. What demand there is, is for lamb, and so quick fattening of milk lambs is important. To test the suitability of Leine sheep for this purpose, 15 ewes of the stud flock of the experimental farm Friedland were chosen as having lambed twice and having ram lambs. Each ewe was stalled separately and each lamb had a box in which it was kept except when allowed to suckle. Milk yield was estimated by weighing the lambs before and after suckling and milk was sampled for analysis when the lamb shifted from one teat to the other; approximately equal amounts were taken from each udder. Feed consumption, by ewe and lamb separately, was accurately recorded. The experiment continued until the lambs weighed 35 to 40 kg.

Lactation lasted for from 105 to 140, mean 129 days. At the end of lactation fat and protein rose steeply and sugar fell. Milk yield was from 99.7 to 135.0, average 118.1 g. daily, with 7.89 per cent. fat, 5.53 per cent. protein and 5.03 per cent. sugar. This is compared with other published data. Data are also given for feed consumed and its computed energy value and for the energy of the milk, from which it is reckoned that 24.82 per cent. of feed energy was recovered in milk.

Data are then presented for total feed consumed by the lambs and for their growth. The mean birthweight was 4.80 kg.; it was doubled in 18 days; the 3-week weight was 10.40 kg. and the 100-day weight 31.40 kg. Other data are quoted for comparison. Mean liveweight of 10 lambs at movement to the slaughterhouse was 37.0 kg., at slaughter 35.0 kg., and carcase weight was 17.8 kg., i.e., killing-out percentage was 50.7. Details are given for weight of the chief cuts. Finally costs of production and value of the lambs are discussed. For profitable production, a lamb crop of at least 106 per cent. would be needed.

KOVAL'SKIĬ, V. V. and PADUCHEVA, A. L. O rezhime vodopoya karakul'shikh ovets v Ukraine. [The regime of giving water to Karakuls in the Ukraine.] *Karakul. i Zver.*, 1954, 7, No. 3, 44-50. [All-Union Sci. Res. Inst. Animal Husb.]

The amount and frequency with which water should be supplied to sheep should be varied in the different climatic zones of the U.S.S.R. and according to the time of year. In winter, for instance, to ewes under cover receiving dry feed, water should be supplied daily during the warm hours of the day and be followed by the daily exercise. Pastured ewes should be given water immediately after the morning supplementary meal before letting them out to pasture. In spring when the air is moist and there is heavy dew on the grass, watering the ewes may be limited to once in 3 days or even less. In summer ewes with lambs should be supplied with water daily and given as much as they can drink. For barren ewes the frequency of the supply of water will depend on the state of the pasture. On dry pastures they should be given water daily. The normal amount drunk by a ewe during the hot period of the year in the U.S.S.R. is about 5 litres daily. The amount of water needed depends also on the breed of sheep.—H. Scherbatoff.

KING, J. W. B. and YOUNG, G. B. A study of three breeds of sheep wintered in four environments. *J. Agric. Sci.*, 1955, 45,

331-338. [Animal Breeding Res. Organiz., Edinburgh.]

Forty-eight ewe hoggs of 3 breeds, Blackface, Cheviot and Wiltshire, were wintered in either a warm or a cold environment, in each on a high or a low plane of nutrition. Little difference was found between breeds in the small growth made on the low plane, but on the high plane the Blackfaces showed relatively greater rate of growth and wool production. Results suggest that certain genotype-environment interactions may exist.

MORLEY, F. H. W., LOCKART, L. W. and DAVIS, E. C. The value of production from a clipped measured area as an index of fleece weight. *Austral. J. Agric. Res.*, 1955, 6, 91-98. [N.S.W. Dept. Agric., Wool Res. Lab., Agric. Exp. Stat., Trangie.]

In a trial with 66 Merino rams and 82 ewes a correlation of 0.58 was found between greasy fleece weight at shearing and wool production of a midside area of 100 sq. cm. Production from this area over 11 months gave little additional information to production over $7\frac{1}{2}$ or $8\frac{1}{2}$ months. Between greasy fleece weight and production per unit area and bodyweight at 11 months the multiple correlation coefficient was 0.79 in rams and 0.71 in ewes. Inclusion of fold score did not add significant information. A table for prediction of greasy fleece weight from the equation

$$W = P_3/100 + B_1/12,$$

where W = greasy fleece weight (lb.) at shearing, P_3 = fleece production up to 11 months after lamb shearing (mg. per sq. cm. skin at 11 months) and B_1 = bodyweight (lb.) at 11 months, is presented for values of P_3 ranging from 250 to 1000 and of B_1 from 50 to 140.—J. C. Gill.

This is chiefly a review, but contains some original observations on Spanish conditions. Sows of the black, Negra lampiña, and red, Colorada extremeña, races are good milkers. In Extremadura and generally in Andalusia and other parts where pigs are bred extensively, the supplementary food supplied to suckling pigs is whole barley, sometimes with a proportion of peas or black chickpeas. Meal is not used, though an experiment is described which showed that 3 litters made much better weaning weights on a balanced meal supplement than comparable litters on barley. The latter is used for practical reasons.

Among Large White \times Colorada extremeña or Negra lampiña pigs the mean number of young born per litter was 6.79, 6.72 live births and 5.57 weaned in spring, summer and autumn, but in winter there were losses from anaemia and diarrhoea. The condition was similar to that described by Howie *et al.* (Abst. 4213, Vol. 19).—D. Duncan.

BERGE, S. and INDREBØ, T. **Composition of body and weight gain of suckling pigs.** *Meld. Norges Landbruksforsk.*, 1954, **34**, 481-500. [Inst. Animal Breeding, Agric. Coll. Norway, Vollebekk.] Norwegian summary.

Pigs were taken from 3 litters at birth and at 1, 2, 3, 4, 6, 8 and 10 weeks old and were analysed for dry matter, ash, crude fat, crude protein, sugar, N, Ca and P. The entire body of each pig from one litter was ground, sampled and analysed; in the other 2 litters the bodies were separated into offal and carcass and these were ground and analysed separately. Milk production of the 3 sows was recorded for the first 4 weeks.

Between birth and 10 weeks old the dry matter content of the entire animals rose steadily from 19 to 34.6 per cent., the fat content from 1.4 to

15.0 per cent., most of the increase being in the first 2 weeks, the energy content per kg. liveweight from 924 to 2330, and the crude protein content from 12.4 to 14.7 per cent.; the percentage of ash, Ca and P remained nearly constant.

The percentages of dry matter and crude protein in the weekly gain remained reasonably constant between birth and 10 weeks old, but the percentage of fat decreased.

In the first 2 to 3 weeks after birth the pigs gained about 0.25 kg. liveweight per kg. milk consumed, but only 0.14 kg. by the fourth week. In the first and second week 60 per cent. of the energy content of the milk was used for liveweight gain, but by the fourth week only 28 per cent.

The dressed carcass percentage fell from 79.6 at 1 week to 77.3 at 8 weeks. The pluck constituted about one-half of the dressing loss of pigs at birth, but the proportion was only one-fourth at 8 weeks old.

During growth from birth to 8 weeks the kidneys and heart were constantly related to liveweight. The proportion of head dropped from 19 to 8.8 per cent., liver from 3.6 to 3.0 per cent. and lungs from 3.0 to 1.2 per cent. The chemical analysis of the offals (the head, feet and kidneys remained on the carcass) was reasonably constant between birth and 8 weeks. They contained 4.0 to 4.5 per cent. crude fat and 12 to 13 per cent. crude protein. During growth 88 per cent. of the gain of energy was in the carcass, about 12 per cent. in the offals.

The material did not allow a statistical comparison of uncut males with females, but the data suggested that the differences were small.

GAWIENOWSKI, A. M., MAYER, D. T. and LASLEY, J. F. **The serum protein-bound iodine of swine as a measure of growth potentialities.** *J. Animal Sci.*, 1955, **14**, 3-6. [Dept. Animal Husb., Univ. Missouri, Columbia.]

A trial with 20 purebred Hampshire gilts and barrows (castrated males) fattened to 215 lb. slaughterweight showed a significant correlation between the serum protein-bound iodine (P.B.I.) and the rate of daily liveweight gain, the latter increasing as the former grew less. There was a similar correlation between P.B.I. and body length. There was a tendency for length of hind leg to be greater and back fat to be less thick as P.B.I. increased, but statistically the differences were not significant. The average P.B.I. value was 3.08 $\mu\text{g.}$ per 100 ml., range 1.2 to 5.4 $\mu\text{g.}$

HEADY, E. O., WOODWORTH, R., CATRON, D. V. and ASHTON, G. C. New procedures in estimating feed substitution rates and in determining economic efficiency in pork production. 1. Replacement rates of corn and soybean oilmeal in fortified rations for growing-fattening swine. *Iowa Agric. Exp. Stat. Res. Bull.* No. 409, May 1954, pp. 895-976. [Ames, Iowa.]

A theoretical study was made of the way in which the weight gain of pigs from weaning onwards depends on the amounts of the 2 main constituents of their diet in Iowa, maize and soya bean oilmeal. There tends to be a decline in the weight gains obtained from successive equal increments in level of feeding and, although it is possible to increase the amount of one dietary constituent and reduce the amount of the other and still obtain the same weight gain, the equivalent amounts of the 2 constituents for this purpose are not constant but depend on their initial proportions in the diet. Several types of non-linear regression equation would provide for this situation in relating weight gain to total feeds of maize and of protein, and equations of 3 of these types have been fitted to the results from 3 separate feeding experiments, for rations with and without aureomycin supplements. The most suitable equation was found to be one in which the logarithm of the weight gain was made a linear function of the maize and protein intakes. Livestock product isoquants are defined as the loci of feed combinations giving constant weight gains, and are derivable from the regression equations. In conjunction with information on the relative costs of the 2 constituents these give the ration combination to produce a given weight gain at minimum cost. In general the least cost ration will vary with the weight of the pig.

The regression equations were used to compile tables intended to be of practical use to the farmer in making decisions on feeding. These are for the most part restricted to the diets containing aureomycin, since the cost of this supplement is very small relative to total feeding costs. They include (1) a table giving the weight gains for varying amounts of diets of varying protein content, with the additional or marginal gains per additional pound of feed; (2) a table showing the weight gains for fixed amounts of protein with varying amounts of maize; (3) a table giving the varying feed combinations which will add 100 lb. weight to pigs of 60, 110 and 175 lb.; and (4) a table giving the food combination to produce a fixed gain at least cost for different possible price ratios of soya bean oilmeal and maize and for 3 different ranges of weight of pig.

The time taken to fatten the pigs was also considered. Non-linear regression equations were

derived which give the time taken to consume given amounts of maize and soya bean oilmeal. These lead to tables showing the time required to take pigs from one given weight to another when fed on diets differing in protein content. The rations which will produce a pig of 225 lb. in minimum time are compared with those which will do it at minimum cost, previously obtained. Fluctuations in the market price of pigs will determine whether a minimum time or a minimum cost ration will be most profitable, and this point is discussed in relation to experience in the United States between 1937 and 1952.—I. McDonald.

WENIGER, J. H. Untersuchungen über den Nährstoff- und Energieansatz verschiedener Schweinerassen im Hinblick auf Lebendgewicht, Tageszunahme und Ernährung. [Storage of nutrients and energy in different breeds of pigs in relation to liveweight, daily gains and diet.] *Arch. Tierernährung*, 1955, 4, 293-331. [Inst. Tierzucht, Martin Luther Univ., Halle, Wittenberg.]

The 102 pigs were mostly Deutsches Edelschwein, improved Landschwein, Cornwall and German Saddleback, with a few Berkshires in the last experiment.

Five newborn pigs had a mean composition of dry matter 18.51, protein 12.37, fat 1.91, ash 4.23 and water 81.49 per cent. The protein : fat ratio was 1 : 0.15.

Nine pigs of the first 3 breeds named, after weaning at 8 weeks, were brought to 30 kg. liveweight on a cereal and potato ration high in protein and were then killed and analysed. The mean daily intakes of protein, fat, minerals and water and the number of calories from each source are tabulated. The third study was similar, but the 11 pigs were brought on the same diet to 40 kg. liveweight. In both studies together the mean intake of 270 g. feed daily contained 35 g. protein and 79 g. fat, and the tissue deposited, obtained by difference between the composition of these pigs and that of the newborn, exactly reflected this ratio. Relative to total weight gain the protein composition rose linearly, and fat deposition was twice that of protein. The mean body composition of the 20 pigs at 30 to 40 kg. was dry matter 41.56, protein 13.01, fat 25.42 and ash 3.13 per cent. There was no breed difference at this stage.

In the fourth experiment, 47 pigs were brought from 40 to 106 kg. liveweight on a standard ration

or one poor in protein. On the normal ration the Edelschweine and Landschweine differed in rate of weight gain, 610 and 639 g. daily, but they continued to deposit protein and fat in much the same ratio, 1:2.8. The Cornwalls and Saddlesbacks, although they received the same amounts of protein, laid down less protein, and variations in feed intake were reflected in variations in fat deposition. Breed differences in body composition became considerable. Pigs on the low-protein diet took a month longer to reach the required weight, so the utilisation of the ration was much reduced. At the low protein intakes of 40 to 50 g. daily, growth became a function of the fat intake, and the tissue deposited had a protein:fat ratio of 1:3.8 in Edelschweine and 1:4.5 in Landschweine. The carcasses therefore had a greater energy content per kg. gained.

Lastly, 30 pigs were brought from 30 to 136 kg. liveweight on a ration of 3 parts barley meal to 2 parts potato flakes, with a protein supplement decreased by stages from 12 to 5 per cent. In Edelschweine and Landschweine in this group the daily weight gain was closely related to fat intake and only indirectly to protein deposition. The optimum protein intake was between 87 and 95 g., with weight gains of 600 to 700 g. daily. When weight gains exceeded 700 g. daily the proportion of fat deposited increased. In the breeds with more tendency to fatten, the change from protein to fat deposition occurred at lower levels.

It is concluded that the profit from producing meat of high quality is to be increased not by increasing daily gains, but by reducing the feed requirement per kg. liveweight gain.—D. Duncan.

ARMSTRONG, D. G. and MITCHELL, H. H. **Protein nutrition and the utilization of dietary protein at different levels of intake by growing swine.** *J. Animal Sci.*, 1955, 14, 49-68. [Div. Animal Nutrit., Univ. Illinois, Urbana.]

Six Hampshire pigs initially weighing 20.6 to 25.7 kg. were used in N balance studies. There were 5 experimental periods and during the first and last diets almost free of protein were used. During the remaining 3 periods the diets contained 4, 10 and 16 per cent. of protein from soya bean oilmeal. The pigs gained weight on the low-protein diets and developed only slight hypoproteinaemia.

By extrapolation to zero of the straight line regression relating faecal N to level of protein in the feed the metabolic faecal N was estimated to be 0.91 g. per kg. dry matter consumed. The value estimated from the use of an almost protein-free diet was 1.14 g. per kg. dry matter consumed. By extrapolation to zero of the straight line regression relating output of urinary N to truly

absorbed N the minimum daily output of endogenous urinary N was estimated to be 106 mg. per $W^{0.754}_{kg}$. The mean value determined from the use of an almost protein-free diet was 133.1 mg. per $W^{0.754}_{kg}$.

The relation of N balance to truly absorbed N up to a level of 10 per cent. protein in the diet was rectilinear, the slope of the regression line expressed as a percentage being 76. This was taken as the biological value of the dietary protein.

Data from other publications indicated that the metabolic utilisation of dietary proteins is similar in rats, pigs and dogs. The biological values of a number of proteins and their essential amino-acid indices were highly correlated.—I. A. M. Lucas.

4376

HANSON, L. E. and FERRIN, E. F. **The value of urea in a low protein ration for weanling pigs.** *J. Animal Sci.*, 1955, 14, 43-48. [Univ. Minnesota, St. Paul.]

In a trial with 69 pigs fattened from weaning to 200 lb. liveweight urea was added to a low-protein ration so that the estimated protein level was that of a normal-protein ration. There was no improvement in growth rate in groups receiving the urea ration compared with those on the low-protein ration, and efficiency was less. The normal-protein ration gave gains 16 per cent. better than the other 2 rations and the pigs were 5 per cent. more efficient than those on the low-protein ration. There was no evidence that urea was toxic, so that no harm would be done by using cattle feeds with 1 to 1.5 per cent. urea in them for pigs, if this should be necessary.—T. D. Bell.

STOLZMAN, M. **Wpływ penicyliny podawanej w paszy na rozwój psiat rasy wielkiej białej angielskiej chorych na grype.** [Effect of an addition of penicillin to the feed on the development of Large White piglets suffering from cold.] *Rocz. Nauk rol. [B]*, 1954, 68, 409-415. [Inst. Zootech., Dziś. Biol. Hodowlanej.] Russian and English summaries.

In 15 Large White piglets $2\frac{1}{2}$ to 3 months old "suffering from cold", weight gains to bacon weight were maintained at almost normal and mortality was decreased by giving 100,000 units non-crystalline penicillin daily in the feed. The treatment did not significantly increase the daily liveweight increase of similar healthy piglets. (From summary).—T. D. Bell.

4378

SMITH, D. M. **Use of antibiotic supplements with separated milk in pig feeding.** *N.Z. J. Agric.*, 1955, 90, 85-88. [Dept. Agric., Animal Res. Stat., Ruakura.]

When penicillin was added to the creep feed of suckling pigs they ate more of this feed and were slightly heavier at weaning than controls, but efficiency of feed conversion was not improved.

With pigs fattened on skimmed milk the addition of penicillin, aureomycin or streptomycin had no effect on growth or efficiency.—T. D. Bell.

4379

JENSEN, A. H., ACKER, D. C., MADDOCK, H. M., ASHTON, G. C., HOMEYER, P. G., HEADY, E. O. and CATRON, D. V. Different protein levels with and without antibiotics for growing-finishing swine: effect on growth rate and feed efficiency. *J. Animal Sci.*, 1955, 14, 69-81. [Iowa Agric. Exp. Stat., Ames.]

In 2 trials involving 288 pigs, rations with 10, 12, 14, 16, 18 and 20 per cent. protein with or without antibiotics were compared. The pigs were fattened from weaning at 31 lb. liveweight to 200 lb. In both trials the protein level affected the rate of gain, the best being 18 per cent. With aureomycin or terramycin the best rate of gain was on the 14 per cent. protein ration. In the first trial efficiency was not affected either by protein level or by antibiotics, but in the second efficiency improved with the improved rate of gain due to protein level. During the early period, 31 to 75 lb. liveweight, in the first trial terramycin increased the rate of gain significantly, but when the fattening period was taken as a whole this advantage disappeared. Over the whole period in the second trial aureomycin increased rate of gain and efficiency, although this was not apparent in the early period.—T. D. Bell.

4380

ASHTON, G. C., KASTELIC, J., ACKER, D. C., JENSEN, A. H., MADDOCK, H. M., KLINE, E. A. and CATRON, D. V. Different protein levels with and without antibiotics for growing-finishing swine: effect on carcass leanness. *J. Animal Sci.*, 1955, 14, 82-93. [Iowa Agric. Exp. Stat., Ames.]

Carcass measurements were made on 2 castrated male pigs from each of 15 groups under different dietary treatments. The pigs were fed from 36 to 200 lb. on fortified maize and soya bean oil-meal rations containing 10, 12, 14, 16 or 18 per cent. protein, each protein level being given alone or with aureomycin or terramycin. The antibiotics were included at 5 mg. per lb. diet. In a second experiment carcass measurements were made on one castrated male and one female pig from each of 12 treatments. The treatments were similar to those in the first experiment except that there was a 20 per cent. protein group, and none of the diets contained terramycin.

The results from both experiments failed to

indicate that antibiotics affected backfat thickness, percentage of lean cuts or sp. gr. of the carcasses. In the first experiment the error variances were large but in the second they were smaller. In the second experiment there were indications that the antibiotics affected the area of loin muscle, but this effect was not consistent between protein levels.

In the first experiment sp. gr. increased linearly with increases of protein in the diet. This was also evident in the second experiment when the figures for backfat thickness, area of loin muscle and percentage lean cuts also indicated that with increases of protein in the diet the carcasses carried less fat and more lean. These changes were of such small magnitude, however, as to be of minor importance when choosing between 2 adjacent protein levels.—I. A. M. Lucas.

4381

HANSON, L. E., FERRIN, E. F., ANDERSON, P. A. and AUNAN, W. J. Growth and carcass characteristics of pigs fed antibiotics for part or all of the growing-fattening period. *J. Animal Sci.*, 1955, 14, 30-42. [Univ. Minnesota, St. Paul.]

One experiment was with 8 groups each of 9 pigs starting at 8 weeks old, and a second was with 8 groups each of 10 pigs, some being started on experiment at 10 weeks and some at 7 weeks. In both experiments the pigs were self-fed on a diet based on maize, soya bean oilmeal and tankage, and in both there were 8 treatments, including one group on the basal meal only. Treatment 2 was with supplementary vitamin B₁₂ and the remaining 6 treatments were with vitamin B₁₂ and either aureomycin, terramycin or procaine penicillin. In 3 treatments the antibiotic was given until slaughter at 200 to 225 lb. and in 3 it was removed from the diet after 125 lb. liveweight. Carcass data were obtained for all pigs in the second experiment.

Before 125 lb. liveweight supplementary vitamin B₁₂ improved growth rate by 10 per cent., but this was not quite significant. The inclusion of antibiotic resulted in a further and significant improvement of 14 per cent. in growth rate, there being no significant difference between the effects of different antibiotics. No treatment had a significant effect on efficiency of feed conversion.

During growth from 125 to 200 lb. supplementary vitamin B₁₂ significantly improved growth rate by 24 per cent. over that of the controls. Pigs receiving aureomycin or terramycin plus vitamin B₁₂ grew slightly faster than those receiving only vitamin B₁₂, but those receiving procaine penicillin did not. However, those receiving only vitamin B₁₂ grew significantly faster than groups which had had terramycin or

N.A. and B., July 1955

penicillin removed from the diets at 125 lb. This removal of antibiotic from diets after 125 lb. had a more marked adverse effect in experiment 1 than in experiment 2. There was no significant effect of treatment on efficiency of feed conversion during this period.

There was no significant difference between treatments for moisture, fat or protein contents of the boned carcasses, although the control pigs were the longest and had the smallest backfat measurements. There was no difference between treatments for quality of cured and smoked wholesale cuts.

It is concluded that antibiotic should be given from weaning to market weight if maximum gains are desired.—I. A. M. Lucas.

4382

WUSSOW, W., WENIGER, J. H. and FUNK, K. Beitrag zur Verfütterung von Streptomycin- und Penicillinmycel an wachsende Schweine. [Streptomycin and penicillin mycelium for growing pigs.] *Arch. Tierernährung*, 1954, Beihefte, No. 5, 223-233. [Inst. Tierzucht, Martin Luther Univ., Halle.]

In a pilot study with 8 pigs streptomycin mycelium had no adverse effect, except that more than 25 g. daily reduced appetite; penicillin mycelium was accepted at levels of up to 200 g. daily.

With 3 groups of pigs, 18 in all, 25 g. streptomycin mycelium daily was given with different protein feeds, fishmeal, yeast and soya bean meal. Two control groups received no protein feed but one had streptomycin; a third control had fishmeal, yeast and skimmed milk but no streptomycin. The mycelium alone was better than no protein supplement, and each of the 3 protein supplements increased its value to about the same extent, but never to that of the high-protein control ration.

It is concluded that vitamin B₁₂ in which the supplements were rich, is not of great value alone, but only when antibiotics are present also.

D. Duncan.

4383

TAYLOR, J. H. and GORDON, W. S. The effect of feeding a diet containing stilboestrol and thyroxine to growing pigs with special reference to the toxicity of stilboestrol. *Vet. Rec.*, 1955, 67, 48-52. [Agric. Res. Coun. Field Stat., Compton, Berks.]

Groups of 6 pigs of liveweight about 50 lb. were fed to 200 lb. liveweight on a basal ration, with no supplement for the control group, or with supplements of stilboestrol (6.0 mg. per lb. feed) and thyroxine (0.3 mg.), aureomycin (0.8 mg.), penicillin (0.8 mg.) or combinations of stilboestrol, thyroxine and one or other of the antibiotics.

Only the antibiotics improved growth rate and efficiency of feed conversion, and this improvement was prevented by stilboestrol and thyroxine.

Toxic signs were produced by the stilboestrol and thyroxine supplement, in some cases proving fatal. The same signs were produced in pigs given a supplement of stilboestrol of 20 mg. per lb. feed without the thyroxine. The signs and post-mortem findings are described. Stilboestrol residues were detected in the urine and flesh of the experimental pigs when preparations were injected into rats or given them to eat.

SCHENDEL, H. E. and JOHNSON, B. C. A study of "growth stimulants" using the baby pig. *J. Animal Sci.*, 1955, 14, 19-23. [Div. Animal Nutrit., Dept. Animal Sci., Univ. Illinois, Urbana.]

In 3 small-scale experiments pigs aged from 48 to 96 hr. were fed on a synthetic milk diet containing 19.5 per cent. solids and 6 per cent. fat.

In experiment 1, which lasted 28 days, aqueous solutions of arsenilic acid, sulphisoxazole and ethomeen C/15 were added to the diet separately or in combination. In experiment 2, also lasting 28 days, a surfactant combination of arquad S, ethomid C/15, ethofat C/15, aerosol CS, aerosol SE and ultrawet K was added to the diet. In experiment 3, lasting 49 days, an antibiotic concentrate No. 802 was added to the diet.

Arsenilic acid significantly increased feed consumption and growth, but ethomeen C/15 and sulphisoxazole given separately did not. Arsenilic acid and sulphisoxazole together tended to increase feed consumption but arsenilic acid and ethomeen C/15 depressed it. In experiment 2 the surfactant combination did not affect performance and in experiment 3 the antibiotic significantly increased feed consumption and growth.

Tissue analysis indicated that the baby pig retains about 3 times as much arsenic in the liver as chicks receiving the same amount of arsenilic acid.—I. A. M. Lucas.

BELLER, K. Zur Frage der Komplettierung der Leistungsfütterung mit Wirkstoffgemischen. [Supplementing production rations with stimulants.] *Arch. Tierernährung*, 1954, Beihefte, No. 5, 216-222. [Inst. Tierheilk., Landwirtschaftl. Hochsch., Hohenheim.]

In 45 practical feeding trials with about 400 pigs in South Germany fattening was successful on reduced rations when yeast extract was supplied; the protein intake could not be reduced, but pla protein could be used to replace animal protein especially in late stages of fattening lard pigs. 33 per cent. reduction in starch value was possib

with a shorter fattening time. There was no adverse effect on quality of carcase.

Two groups of 7 pigs were fattened for 170 days from a total weight of 212 and 219 lb. The experimental group received 24 per cent. less meal and 16.25 per cent. less potato silage than the controls, but with liver and yeast extract [the amount not specified]. For 140 days the weight gains were almost identical, but in the last month the experimental group went ahead and gained at 170 days 1571 lb., against 1445 lb. for the controls. The total consumption of the controls was 4886 lb. meal and 6400 lb. potato silage, and of the experimental group 3711 and 5390 lb.—D. Duncan.

4386

TURMAN, E. J. and ANDREWS, F. N. **Some effects of purified anterior pituitary growth hormone on swine.** *J. Animal Sci.*, 1955, 14, 7-18. [Dept. Animal Husb., Purdue Univ. Agric. Exp. Stat.]

In 3 experiments 11 pigs each weighing about 110 lb. were injected daily with anterior pituitary growth hormone. Seven animals served as controls. Four pigs receiving 4.5 or 6.0 mg. purified growth hormone per 15 kg. liveweight died during the experiment. The remaining animals were slaughtered at 210 to 230 lb. liveweight.

Pigs receiving growth hormone grew slightly, although not significantly, faster than the controls, but their average daily feed consumption was significantly reduced and their efficiency of feed conversion was significantly improved by 19 per cent. They had a lower dressing percentage and their carcasses were longer and carried less fat than the controls. Samples of the edible meat of pigs receiving hormone contained significantly more protein and moisture and significantly less fat than that of the controls.

The pituitaries of pigs receiving hormone contained more thyrotropic and gonadotropic hormones than the control pituitaries. The hormone injections also caused significant increases in blood glucose, but the decreases in blood N.P.N. and slight increases in blood inorganic P were not significant. The inorganic P of the blood of all groups declined with increasing age.

HAVERMANN, H. and RÜTER, H. **Versuche über den Einfluss grenzflächenaktiver Stoffe bei der Fütterung von Schweinen.** [Effect of surface-active substances in pig feeding.] *Arch. Tierernährung*, 1954, Beihefte, No. 5, 60-76. [Inst. Tierzucht, Univ. Bonn.]

Four pairs of pigs were selected from 2 litters so that they were matched in weight and each pair was a male and a female. They received a

practical ration of potatoes, beet pulp, barley meal, oatmeal and fishmeal. For 3 groups surface-active agents, alkylbenzol sulphate and primary alkyl sulphate, were introduced into the diet in gradually increasing quantities. Group 1 received none, group 2 each received about 740 g. of the agents in 206 days, group 3 got 1850 g. in 206 days and group 4 about 180 g. in 66 days, after which they were restored to the control diet.

During the experiment animals of groups 2 and 3 gained on the average 8.0 and 10.5 kg., or 7 and 9 per cent., more than the controls, but those of group 4 gained 6 kg. or 5 per cent. less weight. The effects of the supplement increased with time and were greatest when the pigs had passed 40 kg. bodyweight. The total feed intake was the same in the first 3 groups, slightly less in the fourth, so that weight gain per kg. feed was increased in groups 2 and 3 to the same extent as the absolute weight gain, and the decrease in group 4 was reduced to 4.6 per cent.

At slaughter the losses in all groups were similar. The percentage of fat in the carcase was highest in groups 2 and 3, and so was the yield of meat. The livers were 25 per cent. heavier in group 3 than in controls, and contained some 3 per cent. less water. There was no significant effect on chemical composition or flavour of the meat.

It is concluded that surface-active substances in the concentrations used are harmless to pigs and may be beneficial to older fattening animals.

4388

MÜLLER, R. and MASSEBERG, J. **Der Einfluss von Methionin und Lysin auf den Eiweißwert einer Gerste-Magermilchration bei wachsenden Schweinen.** [Effect of methionine and lysine on the protein value of a ration of barley and skimmed milk for growing pigs.] *Arch. Tierernährung*, 1954, 4, 241-257. [Inst. Anat. Haustiere, Univ. Bonn.]

The protein value (N retained/ N absorbed $\times 100$, where N retained = N absorbed - urinary N and N absorbed = N in feed - faecal N) of the basal ration used on pigs (1750 to 2000 g. barley and 100 g. dried skimmed milk) averaged 61.5 for animals between 40 and 53 kg. in weight, and the biological value 72.2, which is considerably higher than that for barley alone (54 to 58). The experiments thus confirmed the value of milk protein in enhancing the value of cereal protein. Addition of methionine was without effect on protein value or biological value of the given ration in the weight class 30 to 40 kg. Addition of lysine increased the protein value from 61.5 to 71.9 in the weight class 30 to 40 kg., and from 61.9 to 68.2 in animals of about 50 kg. With pigs of 30 kg. the optimum result was attained with 13 g. of DL-lysine sulphate, and with 40-kg. animals

N.A. and R., July 1955

with 10 g. The lysine requirement diminished with increasing bodyweight. In pigs of 60 kg. no improvement in protein value was attained by giving 10 g. lysine.—M. B. Richards.

4389

MINER, J. J., CLOWER, W. B., NOLAND, P. R. and STEPHENSON, E. L. Amino acid supplementation of a corn-cottonseed meal diet for growing-fattening swine. *J. Animal Sci.*, 1955, 14, 24-29. [Univ. Arkansas, Fayetteville.]

Two trials were made to test the value of amino-acid and fishmeal supplements to a basal ration of maize and cottonseed meal, free from gossypol, given to pigs for 4 weeks from weaning. There was a significant growth response to 3 per cent. DL-lysine alone, but in conjunction with 3 per cent. fish solubles, 1 per cent. DL-lysine was better than 3, 2 or 0.5 per cent. or the amino-acid alone. DL-Tryptophan and fish solubles together also produced significant growth response. The response to DL-methionine was not significant. In all cases of growth response there was an increase in efficiency also.—T. D. Bell.

4390

ALDEN, W. G., SANGSTER, R. M. and JONES, M. D. Condensed whale solubles. The evaluation of this by-product of the whaling industry when fed as the animal protein supplement to the rations of pigs and poultry. *J. Dept. Agric. S. Austral.*, 1954, 58, 158-161. [Kybybolite Res. Centre.]

The composition of condensed whale solubles, a pleasant-smelling thick syrup, is given as: moisture 47.3, crude protein 43.1, crude fat 1.3, ash 4.1 and N-free extract 4.1 per cent.

In a feeding trial with 16 weaner pigs, fattened to 160 lb. liveweight, whale solubles were compared with meatmeal, which they replaced on an equivalent protein basis in the rations of 8 of the pigs. Up to 90 lb. liveweight there was no significant difference between the meatmeal and whale solubles groups, but from 90 to 160 lb. liveweight the meatmeal was better.

A further trial was made with 3 groups of 8 weaner pigs fed to 90 lb. liveweight. The groups received rations with the animal protein supplied by 14, 11 or 8 per cent. condensed whale solubles. It was shown that satisfactory growth and efficiency was obtained only at the 14 per cent. level.

With laying pullets 8 pens of 10 birds had the standard meatmeal wet mash, and 8 pens had the meatmeal replaced by condensed whale solubles on an equivalent protein basis. There was no difference between groups in size or number of eggs produced.

The problem of incorporating the solubles in a pre-mixed ration is discussed.—T. D. Bell.

SEIDLER, S. Siano w żywieniu trzody chlewnej. [Hay as a food for swine.] *Rocz. Nauk. rol. [B]*, 1954, 69, 105-128. [Inst. Zootech. ODZ, Bydgoszcz.] Russian and English summaries.

The results of experiments on the use of hay for pig feeding are reported, and rations based on these results are suggested. The method of getting the best hay and the most suitable means of feeding are discussed. (From summary.)—T. D. Bell.

4392

SEIDLER, S. Ziarno słodkiego łubinu w żywieniu trzody chlewnej. [Sweet lupin seed in swine feeding.] *Rocz. Nauk. rol. [B]*, 1954, 69, 129-151. [Inst. Zootech. ODZ, Bydgoszcz.] Russian and English summaries.

Experiments showed that sweet lupins were a useful feed for pigs and could take the place of two-thirds of the animal protein usually given. The composition and nutritive value of different varieties of lupins are reported. Methods of removing the toxic principle from bitter lupins and methods of feeding are discussed. A list of concentrates which have been shown experimentally to be suitable for pigs is given. (From summary.)—T. D. Bell.

4393

FAGAN, V. J. The suitability of fodder beet as a pig food. *Tasmanian J. Agric.*, 1954, 25, 350-357.

Six short-term trials were made in Tasmania. The crop was excellent for the nutrition of breeding stock, but weaners could make good use of it only after they reached 50 to 60 lb. liveweight. An interim recommendation for growing pigs was to give fodder beet plus 1½ lb. crushed wheat and from ¼ to ½ lb. meatmeal per pig daily. In feeding value 4 lb. fodder beet were equivalent to 1 lb. wheat. For weaners the roots had to be sliced or quartered, but this was unnecessary for older pigs. At one farm the beet caused scouring, which may have been associated with either the presence of nitrates in the roots or a high dry matter content.

4394

BIELIŃSKI, K. and BIELIŃSKA, K. Suszona pulpa ziemniaczana jako pasza w tuczu trzody chlewnej. [Dehydrated potato pulp as a feed for fattening pigs.] *Rocz. Nauk. rol. [B]*, 1954, 68, 297-308. [Inst. Zootekh., ZD Kolumbia Wielka.] Russian and English summaries.

Tests were made on 2 groups of pigs of average weight 40 kg. fattened to 90 kg. on a ration of barley, wheat bran, fodder yeast, fishmeal, lucerne hay, potato flakes and dehydrated potato pulp.

The potato pulp constituted 15 per cent. of the ration to start with and was later increased to 20 and to 25 per cent. at the expense of the potato flakes. Average daily weight increases in the groups were 556 and 607 g., showing that daily amounts of 350 g. potato pulp, rising to 800 g., could be given with good results. Of 9 slaughtered animals 7 were graded as class 2 and 2 as class 3. (From summary.)—J. S. Thomson.

4395

HOVORKA, F. Krmení žirných prasat silážovanými brambory ad libitum. [Feeding fattening pigs to appetite on ensiled potatoes.] *Šborn. Čsl. Akad. Zéměd.*, 1954, 27, 597-604. Russian and English summaries.

Experiments showed that when pigs were fed to appetite on steamed potatoes, silage or similar bulky feeds, it was better not to give the concentrates mixed with them, but to give them first, to ensure that none was wasted. The composition of the concentrates should be changed as the pigs grow.

When feeding to appetite it was found that the pigs did not overeat, but satisfied their needs and used the feeds to the best advantage. (From summary.)—T. D. Bell.

WHITING, F. and BEZEAU, L. M. The nutritional value of fire-damaged wheat for swine. *Canad. J. Agric. Sci.*, 1954, 34, 635-638. [Exp. Stat., Lethbridge, Alta.]

Wheat from a burnt grain storage elevator was put through a fanning mill which removed nails, glass, charred wood, charcoal dust and weed seeds, accounting for 14 per cent. of the total weight. The wheat remaining was separated into a sample of grain severely damaged by fire and one of grain less severely damaged. These 2 samples were included in rations and digestion and N balance experiments were made with them, with 4 pigs. The digestibilities of dry matter, organic matter, protein and total energy of the severely damaged wheat were considerably and significantly less than those of less severely damaged wheat and normal wheat. The digestibility of the protein of the less severely damaged wheat was considerably less than that of normal wheat, but otherwise the differences were small. There was little difference between the net utilisation of the protein of the damaged wheats, the values for both being less than for normal wheat. The fire-damaged grain was unpalatable, but the pigs became accustomed to it in a fortnight.—I. A. M. Lucas.

4397

WHITING, F. and BEZEAU, L. M. The nutritional value of frost-damaged and early-harvested

cereal grains for swine. *Canad. J. Agric. Sci.*, 1954, 34, 624-634. [Exp. Stat., Lethbridge, Alta.]

Frost damage significantly reduced the digestibility for weanling castrated pigs of the dry matter, organic matter, ether extract, N-free extract and total energy of wheat. The reduced digestibility of the damaged wheat could partly be accounted for by a higher crude fibre content. Although the digestibility of the protein of severely frosted wheat was lower than in other wheat the utilisation of digested protein was better, and under the conditions of the experiment frost damage did not impair the value of the grain in meeting the protein needs of the body. These results were confirmed in a second experiment in which frost-damaged oats were also tested. The digestibility of the protein of oats, unlike that of wheat, was not reduced by frosting. In a third balance experiment the dry matter, organic matter, true protein, crude fibre, N-free extract and gross energy of early-cut wheat were better digested than the same constituents in frosted wheat, although, with the exception of protein, they were not so well digested as the constituents of wheat cut one week later. The effect of severe frost damage in reducing digestibility was not the same as that of harvesting at the same stage of maturity, probably because the early-cut wheat filled out after cutting and had a lower crude fibre content. There was a significant linear relation between the weight of wheat per bushel and its digestible energy.—I. A. M. Lucas.

4398

GOERTTLER, V. Schädigungen durch von Milben befallenes Futter beim Schwein. [Damage to pigs from mite-infested feedingstuffs.] *Arch. Tierernährung*, 1954, Beihefte, No. 5, 31-34. [Vet. Anst., Friedr. Schiller Univ., Jena.]

Feedingstuffs that have become heavily infested with mites are usually considered toxic and are discarded. Little experimental work is on record. Experiments are described in which a fattening mixture for cattle was cultured in a warm moist atmosphere until it was heavily infested and loaded with mite faeces. From part of this a kg. of clean, live mites was collected (method described).

Six healthy weaned pigs, weighing from 18 to 23 kg. were fed, 2 on potatoes, barley meal and skimmed milk, 2 with the addition of mites, 75 g. from the first to the third day, 20 g. from the fourth to the twelfth day and 123 g. on the 31st day, and 2 with the heavily infested feed in place of barley meal for 32 days. Of the third pair, one had diarrhoea and both had a slight rise of temperature for a few days. Otherwise there was no effect.—I. Leitch.

N.A. and R., July 1955

4399

SEIDLER, S. Wykorzystanie gitii w żywieniu trzody chlewnej. [Use of sarpapel in swine feeding.] *Rocz. Nauk rol. [B]*, 1954, 68, 309-324. Russian and English summaries.

Experiments were made with 32 pigs in 4 groups on a ration of skimmed milk, concentrates, potato flakes, fishmeal and hay meal. On the assumption that 1 kg. sarpapel [lake sludge] was equivalent in feeding value to 100 g. concentrates, fresh sarpapel was given to groups 2, 3 and 4 at the rate of 0.5, 1.0 and 1.5 kg. daily per head, replacing equivalent amounts of concentrates. The highest rate of growth and the best feed utilisation were obtained in group 3. There was no difference between groups in carcase quality. The meat of the pigs given sarpapel took up water slowly and difficulty was experienced in the production of sausage. (From summary.)—J. S. Thomson.

GONZÁLEZ-CHAPEL, A. and CARLO, I. Control of factors increasing the preweaning mortality of swine in Puerto Rico. *J. Agric. Univ. Puerto Rico*, 1954, 38, 205-224. [Dept. Animal Husb., Agric. Exp. Stat., Univ. Puerto Rico, Río Piedras.]

A survey was made of pre-weaning mortality in a herd of 158 sows which produced 382 litters totalling 3841 pigs, of which 35.72 per cent. died before weaning or were born dead. Of the 1372 pigs which died 22.74 per cent. were born dead, 47.52 per cent. died within 1 week of birth, and only 10.06 per cent. died during the second month of the pre-weaning period. Stillbirths and congenital weakness accounted for 61.96 per cent. of the deaths, and 14.66 per cent. were killed by the sows. Of the classifiable diseases scour was the most prevalent, accounting for 4.4 per cent. of the deaths.

Mortality was lower in summer litters because the sows killed more pigs in autumn and winter, and more pigs died during the first week of life in spring, when scouring was an important cause of higher mortality.

Duroc sows farrowed more pigs and more dead pigs and also killed more pigs than Native sows, but the latter lost more pigs during the first week of life. Crossbred litters were more vigorous than purebred Durocs and fewer pigs were farrowed dead, but this hybrid vigour was not so noticeable in the Native crossbreds.

Sows that were 16 to 23 months old farrowed the smallest litters, which also had the lowest mortality. For Duroc sows the numbers of pigs farrowed increased from the first to the sixth litter, but the mortality decreased from the first to the second litter, then increased steadily in subsequent

litters and more than counterbalanced the increase in numbers born. The second litters thus gave the greatest number of pigs weaned.

In most cases the birthweight of pigs that subsequently died was smaller than the average for all pigs. Litters containing 12 or more pigs had a greater mortality during the first 4 weeks of life, not counterbalanced by a lower mortality from the fifth to eighth week. Lower birthweights may have caused the higher overall mortality in larger litters.

Multiple regression coefficients indicated that birthweight exerted relatively the most important direct effect on mortality. For Duroc sows litter number was positively correlated with litter size, which in turn was negatively correlated with birthweight. Age of dam, litter number and litter size were considered to influence pre-weaning mortality through their effect on birthweight.

ALEXANDROWICZ, S., BENEDYKCIŃSKI, S. and KRAUPE, W. Produkcja prosiąt od macior-piervviastek, jednorazowo użytých do rozplodu. [The production of pigs from inipig sows used for reproduction once only.] *Rocz. Nauk rol. [B]*, 1954, 68, 283-296. [Central Board of State Fattening Centres, Lawica, Poznan.] Russian and English summaries.

It is claimed that the breeding of pigs only once, after which they can be rapidly fattened, results in increased production of meat and fat. In this way an average of 8.04 well developed pigs per sow was obtained and the amount of feed used was smaller than in farms producing pigs all the year round. This method is recommended for state farms where there is a lack of proper buildings and staff. (From summary.)

FREDEEN, H. T., BOWMAN, G. H. and STOTHART, J. G. Appraisal of certain methods for evaluation of ham quality. Relationships between certain measurements of ham and carcass quality. *Canad. J. Agric. Sci.*, 1955, 35, 91-94; 95-99. [Dominion Exp. Stat., Lacombe, Alta.]

Data from 181 hams were used to ascertain the most accurate and practicable method of assessing their leanness and quality.

The correlation coefficients between the percentage area of lean on the proximal (open) face of the ham and the percentage lean and percentage fat in the ham were 0.933 and -0.905, respectively. These correlations were higher than others between the percentage lean and percentage fat in the ham and the percentage area of lean from a cross-section of the ham 3 inches distal to the forward

edge of the aitch bone. The percentage area of lean on the open face of the ham was of more value than the absolute area in assessing leanness. Sp. gr. was of less value.

The data strongly suggested that a tapered ham that is more evenly fleshed down to the hook is of a leaner and more desirable type than the present ideal of a plump ham, well filled in the upper portion.

Long hams, which are the leanest, carry the greatest weight of bone. The percentage area of bone on the open face of the ham was highly correlated with the percentage bone of the ham.

The gross correlations between 9 carcass measurements from 181 pigs with the scores and lean, fat and bone contents of the hams are tabulated.

The correlation coefficients between the area of the loin muscle from a cross-section taken at the level of the last rib and the percentage lean in the ham and percentage fat in the ham were 0.794 and -0.723, respectively. The correlation coefficients between measurements of backfat thickness at the shoulder, middle of the back and loin with the percentage fat in the ham were 0.375, 0.508 and 0.464, respectively. The correlations between these 3 backfat measurements with percentage lean in the ham were -0.356, -0.451 and -0.420, respectively. These 3 backfat measurements were more highly correlated with the percentage area of lean on the proximal (open) face of the ham than with the area of the loin muscle, and this was taken to indicate that the percentage area of lean on the open face of the ham is a better indication of general carcass leanness than is the area of loin muscle.

The score for the proportions by weight of the main cuts in the carcass, i.e., "balance", was not a useful measure of ham quality and accounted for only 13 per cent. of the variance in ham weight. However, the predictability of the percentage lean in the ham was 51 per cent. from loin area and 57 per cent. from the percentage lean on the open end of the ham, and a combination of these 2 measures by a multiple correlation technique raised the predictability to 72 per cent.

It is suggested that the inclusion of a measure of ham leanness in routine carcass evaluation would serve the dual purpose of providing an

objective measure of ham quality and of placing greater emphasis on the quantity of lean meat in the entire carcass.—I. A. M. Lucas.

PALACIOS REMONDO, J. Ganado porcino "Baztán". Resumen de los resultados de una experiencia de alimentación controlada, llevada a cabo en un lote aborigen en "habitat" de aclimatación. [The Baztán breed of pigs. Summary of the results of a controlled feeding experiment on an aboriginal group in an adopted habitat.] *An. Inst. Invest. Vet., Madrid*, 1953, 5, 55-59. English and German summaries.

Five pigs of the Baztán breed, 2 months old and weighing 24 to 27 kg., were selected as of average type from a herd of 30. They were fed on a ration containing, per cent., whole wheat meal [salvado-harina de trigo] 40, barley 22, wheat bran [salvado-trigo] 10, beans 15, fishmeal 9, bonemeal 2, and vitamin and mineral supplement 2; the digestible protein content was 10.7 per cent.

The mean feed consumption per 100 kg. live-weight gain was 360 kg. The daily consumption per kg. gain was 2.6 kg. in the first 3 weeks, rising to 4.75 kg. between the 42nd and 70th days and then falling to 4.0 kg. up to the 92nd day. The mean daily live-weight gains in the same 3 periods were 540, 640 and 840 g., and for the whole experiment 700 g. The final liveweights were 85 to 94 kg., and the carcass yield in 3 pigs was 82 per cent.

D. Duncan.

VVEDENSKAYA, A. E. Sezonnnye izmeneniya v ispol'zovanii korma serebristochernymi lisitzami. [Seasonal changes in the utilisation of feed by silver foxes.] *Karakul. i Zver.*, 1954, 7, No. 4, 35-38.

Foxes utilise protein better in the summer and fats and carbohydrates in the autumn, since they need to lay up a store of fat for the winter when they may have to endure long periods of starvation. This accumulation of protein in the summer and fat in the winter was independent of the level of nutrition and the protein content of the ration. A decrease in the protein content of a ration providing adequate energy reduced the digestibility of all nutrients at all seasons.

H. Scherbatoff.

4407

ROMANOVSKII, D. M. Krolikovodstvo (iz opyta raboty nauchno-issledovatel'skogo instituta krolikovodstva i zverovodstva). [Rabbit rearing (from the experience of the Scientific Research Institute of Rabbit and Animal Rearing).] *Priroda*, 1954, No. 5, 56-62. [Sci. Res. Inst. Rabbit and Animal Rearing.]

The most valuable components of rabbit meat are the nitrogenous compounds. The protein content of rabbit meat is 21.47 per cent.; that of average beef is 20.58, fat mutton 16.36, poultry 19.3, fat pork 14.54, lean pork 20.08 per cent. The fat content of rabbit meat varies between 8 and 19 per cent. The quality depends on the time of year, the best being after the end of the autumn moult and before the onset of the winter frosts. Carcase weight is about 50 to 60 per cent. of liveweight and in well fed rabbits is up to 70 per cent. and more.

Rabbit's milk contains 10 to 20 per cent. protein, 14 to 26 per cent. fat and about 2.5 per cent. mineral matter.

A doe of 4 kg. liveweight should receive during the winter 135 feed units (1 feed unit being the

feeding value of 1 g. oats) and 10 g. digestible protein; during the lactation period these amounts should be increased up to 345 feed units and 35 g. digestible protein. Young rabbits of 1 to 5 months should receive 100 to 200 feed units and 10 to 19 g. digestible protein. The daily ration is worked out according to these standards. Thus an adult rabbit of 4 kg. liveweight would receive in winter 150 to 200 g. hay, 200 to 250 g. succulent foods, i.e., carrots, beet, turnips, potatoes, 30 to 40 g. concentrates. During lactation the amounts of succulent foods and concentrates would be doubled. Young rabbits of 1 to 5 months are given hay in winter, 50 to 200 g. according to age, 110 to 300 g. succulent foods and 30 to 40 g. concentrates. Green food (good leafy grass) is the best food for rabbits in summer, hay in winter. Rabbits also eat twigs such as those of acacia and maple. The best concentrates are oats; maize, barley, peas, soya and bran can also be given.

Adults should be fed 3 to 4 times a day, young rabbits 5 to 6 times. Bran should be moistened or, better, mixed with root vegetables. Vitamins, such as are found in green food, are important for rabbits, particularly those in legumes, red carrots, good hay which has retained its green colour, and sprouted oats.—H. Scherbatoff.

HUANG, T. C., ULRICH, H. E. and McCAY, C. M. Antibiotics, growth, food utilization and the use of chromic oxide in studies with rabbits. *J. Nutrition*, 1954, 54, 621-630. [Dept. Animal Husb., Animal Nutrit. Lab., Cornell Univ., Ithaca, N.Y.]

Neither terramycin, nor aureomycin with vitamin B₁₂, as a supplement at the levels usually given to other animals stimulated the growth of rabbits given a standard pelleted ration, or a purified ration with 25 per cent. casein or 24.7 per cent. soya protein plus 0.5 per cent. methionine. Even when the casein was reduced to 10 per cent., with or without nicotinic acid, a diet insufficient to meet the requirements for growth, terramycin did not give any improvement.

Chromic acid was a suitable indicator for digestibility trials when a 5-day preliminary period was allowed.

The utilisation of protein and dry matter was improved by refection. Crude fibre was digested and vitamin B₁₂ synthesised in the caecum.

In these trials rabbits required 2.7 g. dry matter intake to produce 1 g. liveweight increase from weaning to 6 weeks of age or 3.7 g. from weaning to 12 weeks.—T. D. Bell.

BENTON, D. A., HARPER, A. E. and ELVEHJEM, C. A. The need for supplemental tryptophan in semi-purified diet for chicks. *Poultry Sci.*, 1954, 33, 1279-1280. [Dept. Biochem., Univ. Wisconsin, Madison.]

In earlier studies (Abst. 3015, Vol. 25) it was demonstrated that chicks on a semi-purified diet containing 18 per cent. casein and 10 per cent. gelatine as the protein sources and sucrose as the sole source of carbohydrate grew at a sub-optimum rate, and that growth could be improved either by increasing the proportion of casein in the ration or by using dextrin in place of sucrose.

In further trials chicks receiving the "sucrose plus 18 per cent. casein" diet weighed 279 g. at 4 weeks of age, and others that received the same ration supplemented with 0.2 per cent. of DL-tryptophan had a significantly higher mean weight of 333 g. Chicks that received a "sucrose plus 25 per cent. casein" ration alone, and with added tryptophan, weighed 352 and 339 g., respectively.

It is concluded that biological estimations of "unknown growth factors" in crude materials may be invalidated by the contribution of tryptophan from the materials where basal rations of the "sucrose plus 18 per cent. casein" type are used.—K. J. Carpenter.

KLAIN, G. J., HILL, D. C. and SLINGER, S. J. Supplementation of poult diets with lysine. *Poultry Sci.*, 1954, 33, 1280-1282. [Dept. Nutrit., Ontario Agric. Coll., Guelph.]

Four groups, each of 10 poults, were fed from hatching to 4 weeks of age on a ration of soya bean oilmeal 19, fishmeal 2.5, meatmeal 2, dried buttermilk 2, minerals 5.26, tallow 1, vitamin supplements, procaine penicillin, 3-nitro-4-hydroxy-phenylarsonic acid, DL-methionine 0.115, maize-meal 15 and ground wheat to 100. Their mean finishing weight was 473 g., and 70 per cent. showed the white feathering believed to be characteristic of lysine deficiency. Parallel groups received the same ration supplemented with 0.68 per cent. L-lysine hydrochloride and their mean weight was 587 g.

These rations contained 21.8 per cent. crude

protein; similar rations containing additional soya bean meal to raise the crude protein content to 25.5 per cent. and with only 0.065 per cent. added methionine gave birds weighing about 600 g., both when no lysine was added and when a supplement of 0.29 per cent. was included. Finally, poults on a ration containing sufficient soya bean meal, added at the expense of wheat, to raise the crude protein content to 28.8 per cent. and with only 0.025 per cent. of added methionine, had a mean weight at 4 weeks of 625 g. This high-protein ration was found on analysis to contain approximately 1.75 per cent. lysine, which was also the level of total lysine in the 2 rations of lower protein content that were supplemented with this amino-acid.—K. J. Carpenter.

4412

MILLER, E. C., SUNDE, M. L., BIRD, H. R. and ELVEHJEM, C. A. The isoleucine requirement of the laying hen. *Poultry Sci.*, 1954, 33, 1201-1209. [Dept. Poultry Husb., Univ. Wisconsin, Madison 6.]

Four White Leghorn pullets were housed in laying cages and given a ration of bloodmeal 23, glycine 1, L-arginine 0.25, DL-methionine 0.1, condensed fish solubles 1, minerals 5, oil 3, vitamins and dextrin to 100, which was calculated to contain 0.28 per cent. L-isoleucine. This group stopped laying completely within 2 weeks. A second group that received the same ration supplemented with 0.6 per cent. DL-isoleucine continued to lay for 8 weeks, but only at a much reduced rate.

In further trials, groups of birds received another ration, of bloodmeal 11.75, ground wheat 20, ground maize 20, wheat bran 10, lucerne meal 4, glycine 0.8, L-tyrosine 1, L-arginine 0.2, oil 3.5, minerals 5, vitamins and dextrin to 100, calculated to contain 0.4 per cent. L-isoleucine (although only 0.33 per cent. was found by microbiological estimation). These birds also showed a severe decline in egg production over a 7-week experimental period. Yet, 2 groups that received the same ration supplemented with 0.4 per cent. DL-isoleucine continued to give 70 per cent. production, and they did not lose weight heavily, as did the groups that received the ration without supplement; 0.3 per cent. isoleucine appeared to be only slightly less effective, but 0.2 per cent. was inadequate.

All the pullets were artificially inseminated and a study of hatchability indicated that this was not significantly reduced when the rations were inadequate for a normal rate of egg production. The chicks grew normally after hatching.

HOHLS, H. W. Über Küken-Fütterungsversuche zur Bestimmung der biologischen Wertigkeit von Eiweiss und deren Abhängigkeit vom Alter der Versuchstiere. [Chick feeding experiments to estimate the biological value of protein and its dependence on the age of the experimental animals.] *Arch. Geflügelk.*, 1955, 19, 1-12. [Bundesforschungsanst. Kleintierzucht, Celle.] English summary.

In all, 35 groups each of 20 day-old chickens were fed for 5 to 8 weeks on 12 different diets. Two diets contained 16 per cent. plant protein with or without 2 g. penicillin per ton; 3 contained 14 per cent. plant and 2 per cent. animal protein, with 0, 2 or 5 g. penicillin per ton; 4 contained 11 per cent. plant and 5 per cent. animal protein, with 0, 2, 5 or 8 g. penicillin per ton; and 3 contained 8 per cent. plant and 8 per cent. animal protein, with 0, 2 or 5 g. penicillin per ton. The biological value of the protein in each ration was estimated at intervals.

With all the proportions of plant and animal protein the biological value was less after 8 weeks than initially, but the fall was not always continuous. The initial value was sometimes as high as 100 per cent., but the data for the first week were omitted because of the utilisation of yolk sac protein at that time.—D. Duncan.

BRELY, J. and MARCH, B. Fat studies in poultry. 2. Fat supplements in chick and poultr rations. *Poultry Sci.*, 1954, 33, 1220-1227. [Poultry Nutrit. Lab., Univ. British Columbia, Vancouver.]

New Hampshire chicks were reared to 6 weeks of age on a control ration of fishmeal 9, dried liver 3, dried brewer's yeast 2, soya bean oilmeal 18, mineral, vitamin and antibiotic supplements and equal parts of ground maize and wheat to a total of 93 parts. The mean finishing weight of these birds (males and females) was 702 g. Further groups that received 93 parts of the control ration and 7 parts of either cellulose, tallow or maize starch had mean weights of 679, 698 and 687 g., respectively. The feed to gain ratios on the control and the supplemented rations were 2.21, 2.22, 1.90 and 2.06, respectively.

In a second trial where the birds were reared to 7 weeks of age, groups that received the supplemented rations containing either maize starch or tallow finished at 784 and 796 g., respectively. Parallel groups received similar rations but with the protein content raised from 24 to 29 per cent. by the addition of 6 parts of soya bean oilmeal and 3 parts of fishmeal at the expense of the maize and wheat. These groups had mean finishing weights of 817 g. with maize starch and 850 g.

with tallow. In further groups where the protein content of the rations had been reduced to 19 per cent. the addition of tallow appeared to have a depressing effect on growth.

In a further experiment turkey poults were fed from hatching to 10 weeks of age on a series of experimental rations. The control diet contained 28 per cent. protein: it was of a type similar to that used with the chicks but contained 23 per cent. of animal by-products. The males receiving this ration had a finishing weight of 2550 g. and the females 1860 g. Parallel groups that received a 32 per cent. protein ration for the first 2 weeks and were changed to 29, 26, 23 and 20 per cent. protein rations at 2, 4, 6 and 8 weeks of age finished only 4 per cent. lighter in weight than those on the first ration. The addition of 2, 4, 6 and 8 per cent. tallow to the latter rations in the successive stages did not result in any stimulation of growth, but was accompanied by a 5 per cent. improvement in feed conversion efficiency. The incorporation of tallow at these levels in a series of rations all containing 32 per cent. protein, and in another experiment in rations containing 28 per cent. protein, had no consistent effect in improving either growth rate or efficiency of feed conversion.

WILGUS, H. S. (Jr.), GASSNER, F. X., PATTON, A. R. and HARSHFIELD, G. S. The iodine requirements of chickens. *Colorado Agric. Exp. Stat. Tech. Bull.* No. 49, May 1953, pp. 81. [Fort Collins, Colo.]

A series of experiments were made through successive generations. Growth, efficiency of feed utilisation, mortality, egg production, egg weight, egg quality, fertility, hatchability, behaviour of offspring and thyroid weight, histology and iodine content were studied.

Goitre, which was most critically indicated by thyroid histology, was the main effect of I deficiency, but even severe goitre did not necessarily cause impaired behaviour, appearance or efficiency of feed utilisation.

The minimum requirements for I were 0.5, 0.1 to 0.5 and 0.5 mg. per lb. feed for growing chickens, laying hens and breeding hens, respectively, but the tolerance for I was high, at least 227 mg. per lb. feed for growth to 6 weeks, 81.8 mg. for growth to maturity and for egg production, and 22.7 mg. for hatchability. The use of iodinated casein in excessive amounts stimulated feather development, but impaired hatchability, efficiency of feed utilisation and the quality and viability of the chickens hatched.

As a practical recommendation it is suggested that rations should contain at least 0.5 mg. and preferably 0.75 to 1.0 mg. I per lb.—T. D. Bell.

4416

FRÖLICH, A. Effectiveness of DL-methionine in overcoming the deleterious effects of insufficiently heated soybean oil meal to growing chicks. *Acta Agric. scand.*, 1954/55, 5, 3-10. [Nat. Animal Exp. Stat., Upsala.]

Two rations used for a chick feeding trial were each made up of soya bean oilmeal 16.6, sunflower seed oilmeal 4, lucerne meal 4, minerals 4.1, oils rich in vitamins A and D, vitamin supplements rich in riboflavin, nicotinic acid and vitamin B₁₂, maize meal 20.5, wheat bran 11 and grits (barley and oats) to 100; they differed in the type of soya bean meal used. Meal B had been fully heat-treated and showed no urease or antiproteolytic activity in laboratory tests; the other meal, C, had received less heating during manufacture and gave positive results in both tests.

Duplicate groups, each of 20 chicks, that had received meal B from hatching to 4 weeks of age had a mean weight gain of 200 g., those that had received meal C of 157 g. Corresponding groups that had received the rations containing either meal B or C supplemented with 0.15 per cent. DL-methionine had mean weight gains at 4 weeks of 206 and 197 g., respectively. At 8 weeks of age the chicks receiving meal C plus methionine were as heavy as those receiving meal B with or without the addition of methionine; those receiving meal C alone were significantly lighter.

In a further trial in which the meals were compared as ingredients at a lower level (10 per cent.) in a ration that also contained 6.3 per cent. fish-meal, the group receiving meal B was only 5 per cent. heavier, at 8 weeks of age, than the group that had received meal C.—K. J. Carpenter.

AUXILIA, M. T. Effetto del metiltiouracile associato all'aureomicina nell'ingrassamento di giovani polli "New Hampshire". [Effect of methylthiouracil with aureomycin on the fattening of young New Hampshire chickens.] *Ann. Sper. agrar.*, 1954, 8, 1239-1245. [Centro Avicolo Sper., Turin.] English summary.

As a supplement to increase the efficiency of feed utilisation of chickens, methylthiouracil reduced appetite, so that no advantage was gained. An experiment was made with 22 New Hampshire chickens 35 days old. Half of the birds received a supplement of Aureofac and methylthiouracil. After 4 weeks these birds had reached a liveweight of about 1 kg. and had eaten 14 per cent. less feed than the control birds, which then weighed only 890 g. and took another week to reach the required weight of 1 kg.

The experimental birds had slightly more internal fat and their livers were larger and paler.

WAIBEL, P. E., ABBOTT, O. J., BAUMANN, C. A. and BIRD, H. R. Disappearance of the growth response of chicks to dietary antibiotics in an "old" environment. *Poultry Sci.*, 1954, 33, 1141-1146. [Dept. Poultry Husb., Univ. Wisconsin, Madison.]

In a series of trials over an 18-month period, groups of chicks were fed from hatching to 3 weeks of age on a ration of soya bean oilmeal 32, wheat offals 10, lucerne meal 5, minerals 2.5, choline chloride 0.2, an oil rich in vitamins A and D 0.2, riboflavin, vitamin B₁₂ and yellow maize meal to 100. The mean finishing weights of the group ranged from 132 to 221 g. Parallel groups that received the same ration supplemented with 15 mg. procaine penicillin G per kg. were from 3 to 38 per cent. heavier than the corresponding unsupplemented group.

Other groups received these rations supplemented with mixtures of the known vitamins, condensed fish solubles, a dried liver preparation, yeast and whey; but these did not affect growth significantly, and the response to penicillin was of the same order as with the less complex ration.

Rather faster growth was obtained with a semi-purified ration containing casein, gelatine and dextrin with mineral and vitamin supplements, the mean finishing weight being about 240 g. without penicillin, and 2 to 22 per cent. higher with it.

Over a further period of 12 months in which generally similar, though not exactly corresponding, rations were given in the same room and with the same equipment, there was no consistent tendency for procaine penicillin to stimulate growth. In general it seemed that the rations without penicillin at this time gave mean weights of the order of those previously obtained only with the addition of the antibiotic. It is suggested that this may have been due to a modification of the microbial flora of the room over the period of the trials. The results contrast with those reported elsewhere in which the response to antibiotics in a house not previously used for poultry has generally increased as successive trials were carried through.

K. J. Carpenter.

HOHLS, H. W. Die wachstumsfördernde Wirkung des Penicillins bei der Kükenaufzucht. [Growth-accelerating action of penicillin in chicks.] *Arch. Geflügelk.*, 1954, 18, 304-326. [Bundesforschungsanst. Kleintierzucht, Celle.] English summary.

Four trials are reported, over periods ranging from 37 to 57 days, with, in all, 35 groups of 20 Leghorn chicks, reared on wire floors. In the first, 2 or 14.5 g. penicillin per metric ton was added to a basal all-vegetable ration, with crude protein

N.A. and R., July 1955

content 12.6 per cent., of ground sweet lupins 25, ground sugar beet slices 20, finely ground oats 20, wheat bran 12, ground wheat 10, ground barley 10, and minerals, including trace elements Fe, Cu, Mn and Co, 3 per cent. In the second, the basal ration was the same except that sugar beet slices were replaced by potato slices, reducing the crude protein to 11.3 per cent., and vitamins A and D were added as 9 g. Dohyfral A + D₃ per 50 kg. feed. To this was added 2 g. penicillin with or without 2 mg. vitamin B₁₂, or twice these amounts, per metric ton. In the third, there were 4 basal rations, with crude protein contents ranging from 16.8 to 15.4 per cent., an all-vegetable one of ground soya grits 23, ground husked oats 15, ground maize 15, ground husked barley 15, ground wheat 13, wheatfeed 10, lucerne meal 4, wheat germ 2, minerals 3 and vitamins as in series 2, and 3 with 2, 5 or 8 per cent. animal protein from cod meal and less soya grits and more wheatmeal and ground wheat. To these were added, respectively, 2; 2 or 5; 2, 5 or 8; and 2 or 5 g. penicillin per metric ton. Trial 4 was a repeat of trial 3. In all trials there was a control group on commercial feed.

The final weights are tabulated. None of the groups equalled those on commercial feed; only those with the 2 highest levels of animal protein were comparable. Penicillin improved the all-vegetable rations, less when vitamin B₁₂ was added. With rations containing animal protein the results were variable and in some groups the effect was nil or even adverse. The effect of penicillin was less, but more consistent, as the proportion of animal protein increased. As was found by workers in the U.S. (see e.g., Absts. 2506, 5294, Vol. 23) the variations were associated with differences in feed intake. The differences in feed intake were partly ascribed to chance and partly to different amounts of animal protein in the ration (Hohls, *Deutsch. Kleintier-Züchter*, 1954, No. 5, 3) but it was thought that there was a real effect of penicillin on feed intake.

More careful study pointed to an effect of penicillin also on intermediary metabolism through an increase in the biological value of protein. Respiratory quotient measurements made twice a week by the author's method (Abst. 4702, Vol. 24) showed a reduction of net energy required per g. weight gain when 2 g. penicillin per ton was added to the ration with 2 per cent. animal protein and a greater reduction with 5 g. penicillin; with 5 per cent. animal protein this effect was not found. The data also showed an increase in biological value of the protein as the proportion of animal protein increased. Since neither effect increases indefinitely, it is considered that this explains why the effect of penicillin decreases as the proportion of animal protein increases.—W. M. Deans.

Vol. 25, No. 3

WHITE-STEVENS, R. and ZEIBEL, H. G. The effect of chlortetracycline (aureomycin) on the growth efficiency of broilers in the presence of chronic respiratory disease. *Poultry Sci.*, 1954, 33, 1164-1174. [Res. Div., American Cyanamid Co., Pearl River, N.Y.]

In a series of practical trials, with about 1000 birds per group, meat-type chicks were reared to 12 weeks of age under conditions where chronic respiratory disease was established.

In one case, when the control birds received a practical ration containing 4 g. procaine penicillin per ton, mortality was 11 per cent. and the mean finishing weight of the survivors was 2.9 lb. Birds in groups that had received the same ration supplemented with 100 g. aureomycin hydrochloride per ton had only 3 per cent. mortality and weighed 3.1 lb.

In another, when high levels of aureomycin began only at 6 weeks of age after an outbreak of disease had become evident, control birds had 11 per cent. mortality and a finishing weight of 3.3 lb. Others that received 100 or 200 g. aureomycin hydrochloride per ton mash had 6 and 5 per cent. mortality, and weighed 3.3 and 3.5 lb., respectively. Similar or slightly better results were obtained with 400 g. per ton mash for 14 days and then continuing at the level of 100 g. per ton, or alternatively of adding aureomycin to the drinking water only at the rate of 250 mg. per gal. for 14 days.

In other trials there was no outward sign of the disease until the birds were 10 weeks old. Up to this time birds receiving the ration supplemented with 50 g. aureomycin per ton of their ration and in addition having their drinking water fortified with 250 mg. aureomycin per gal. were no heavier than those that received aureomycin only in their ration; but when the disease became epidemic those receiving the fortified drinking water were the less affected.—K. J. Carpenter.

ABBOTT, O. J., BIRD, H. R. and CRAVENS, W. W. Effects of dietary arsanilic acid on chicks. *Poultry Sci.*, 1954, 33, 1245-1253. [Dept. Poultry Husb., Univ. Wisconsin, Madison.]

Over a period of 17 months successive trials were made in the same rearing house, with cleaning and disinfection in the intervals. In each trial control chicks were reared to 3 weeks of age on a constant basal ration of soya bean oilmeal 36 parts, mineral supplements 6.5, vitamins and maize meal to 100.

In the first trial the control chicks finished with a mean weight of 129 g.; those that received the basal ration supplemented with 10 mg. procaine penicillin per kg. were 19 per cent. heavier, and those that received the basal ration supplemented with 30, 60 and 90 mg. arsenilic acid per kg. were, respectively, 21, 32 and 11 per cent. heavier than the controls. The same order of response to these supplements was not obtained in later trials, and in the second half of the series the mean weights of the groups receiving either procaine penicillin or arsenilic acid were always within the range of 97 to 105 per cent. of the weight of the control birds.

In a separate series of chick growth trials, in which a semi-purified diet was used, with casein and gelatine as the protein sources and dextrin as the source of carbohydrate, it is stated that the addition of either 20 or 90 mg. arsenilic acid per kg. to the ration reduced to some extent the vitamin B₁ deficiency of chicks receiving the ration unsupplemented, i.e., with a vitamin B₁ content of only 1.2 mg. per kg. Procaine penicillin had the same effect as arsenilic acid.

Lastly, in toxicity trials, arsenilic acid was given as a supplement, at different levels, to a soya bean and maize meal ration of the type used in the first series of trials. A level of 500 mg. per kg. in the ration had no effect on chick growth in 70 days, although there was no evidence of the growth stimulation observed with lower levels of the drug. With 1500 mg. arsenilic acid per kg. ration growth was severely depressed and with 2000 mg. per kg. there was high mortality, mostly in the first fortnight. The toxic signs resembled those seen in vitamin B₁ deficiency, except that the chicks retained their appetite.—K. J. Carpenter.

4423

LORENZ, F. W. Effects of estrogens on domestic fowl and applications in the poultry industry. *Vitamins and Hormones*, 1954, 12, 235-275. [Dept. Poultry Husb., Univ. California, Davis.]

KLIESCH, J. and BORMANN, G. Untersuchungen über die Wirtschaftlichkeit der Hähnchenkastration bei Anwendung der hormonalen Kastration. [Economics of rearing cockerels when hormonal castration is used.] *Arch. Geflügelk.*, 1954, 18, 469-486. [Inst. Tierzücht., Tech. Univ., Berlin.] English summary.

World literature is reviewed. An 8-week experiment made in 1952 is described, with 3 groups of 90 Leghorn cockerels, 8, 10 and 12 weeks old, each divided into 3 sub-groups for comparison of 3 different hormone preparations, and an untreated group of 30. They were self-fed on commercial

poultry meals, with grain, carrots and a daily wet mash of cooked potatoes, wheat bran, ground oats, chopped green feed and sour skimmed milk, but were not specially fattened.

Weight gains were only slightly increased by treatment, but breast development and tenderness of flesh were improved. Studies on the nature of the effect of hormone treatment on the flesh are in progress. The average feed consumption per bird over 16 weeks was 4.6 kg. mixed feed and grains and 2.4 kg. potatoes, and the average final live-weight was 1395 g. in the group treated at 8 weeks. The day-old cockerels cost 0.20 DM., feed 2.76 DM., electric heating 0.12 DM. and labour 0.30 DM., and hormone treatment 0.50 DM. per bird. The selling prices in Berlin were 4.55 and 5.50 DM. and profits per bird 1.17 and 1.62 DM. for untreated and treated birds, respectively. It is concluded that hormone treatment is commercially worth while in feeding the 15 to 18 million cockerels, mainly of the Leghorn and Italian breeds, yearly produced in Western Germany.

HELDER, J. F., FRINGS, H. M. K. and UBBELS, P. Zetmeelhoudend weipoeder in opfokvoeder voor kuikens. [Starchy dried whey in a chick starting mash.] *Rijksinst. Pluimveeteelt, Beekbergen, Med.* No. 55, pp. 8. English summary.

To make use of whey from which lactose has been removed, an equal weight of barley meal is added and the mixture is dried on rollers and ground. To equalise protein intake when it is compared with dried whey, 0.6 per cent. herringmeal is added to the ordinary whey.

The test was made with 18 groups of 20 North Holland Blue chicks in batteries on mesh floors. The starting mash was of meals, buckwheat, barley, yellow maize, oats, wheat, sesame and sunflower seed, herringmeal, dried whey of the different sorts, brewer's yeast, vitamins A and D₃, minerals and iodised salt. Mean weights at 10 weeks were for cocks on ordinary whey, 1291 ± 13.5 g., on starch-whey 1306 ± 13.5 g. and for hens 1173 ± 13.9 and 1193 ± 14.3 g.—I. Leitch.

4426

KLEIN, F. W. and BARLÖWEN, G. v. Tapiokamehl im Aufzuchtfutter. [Tapioca meal in the rearing ration.] *Arch. Geflügelk.*, 1954, 18, 415-428. [Lehranst. Kleintierzucht, Ki.-S.] Steenbek.] English summary.

Two trials were made with tapioca meal of Eng.-following percentage composition: moisture ash 1.3, crude protein 1.3, crude fat 0.1 ranging fibre 1.4, nitrogen-free extract 81.7. aps of 20

Four groups of 30 day-old chicks were. In the 8 weeks on a basal all-mash ration 0 was added ground maize 30, ground wheat 30, wide protein

N.A. and R., July 1955

15, lucerne meal 3, dried yeast 3, cod meal 8, soya grits 8, calcium carbonate 1.2, calcium phosphate 1.2, salt 0.6, Dohytral extra A + D₃ 0.02, manganese sulphate 0.025 per cent., or the same with the maize and wheat equally reduced and 10, 20 or 40 per cent. of tapioca meal replacing them. The digestible protein contents of the rations were 16.54, 15.77, 14.98 and 13.42 per cent. The mean weights at 8 weeks were 529.7, 474.3, 409.1 and 431.0 g., respectively. Feed intake and efficiency of feed utilisation were reduced by the tapioca meal.

In the second trial New Hampshire chicks had a basal ration as before except that the bran was replaced by wheat feed, and in the experimental groups more wheat feed was given so as to compensate for the low protein content of the tapioca meal. This time the weights at 8 weeks were 676.0, 634.0, 588.5 and 456.0 g., respectively. Feed intake was reduced in the groups given 20 or 40 per cent. tapioca meal; efficiency of feed utilisation was only slightly affected.

It is concluded that tapioca meal contains something which reduces feed intake and that not more than 10 per cent. should be included in chick rations and special care should be given to the balancing of the ration.—W. M. Deans.

4427

WEETH, H. J. and ROSENBERG, M. M. Effect of cane final molasses on certain cations in the serum and bones of chicks. *Poultry Sci.*, 1954, **33**, 1135-1140. [Dept. Animal Husb., Univ. Hawaii, Honolulu.]

Tests are reported on the effects of feeding to chickens a sample of blackstrap molasses containing 9.9 per cent. ash, 0.22 per cent. Ca, 0.39 per cent. Mg and 3.30 per cent. K.

Control chicks received either ration 1, of herringmeal 7, soya bean oilmeal 22.5, lucerne meal 3, bonemeal 1.5, salt 0.5, vitamins, aureomycin and yellow maize meal to 100; or ration 2, of similar composition, but with 0.5 per cent. ground oyster shell and an additional 0.5 per cent. bonemeal to give a higher level of Ca. The test ration, 3, was of herringmeal 9, soya bean oilmeal 24, lucerne meal 3, blackstrap molasses 23, bagasse pith 2.3, bonemeal 0.5, vitamins and aureomycin (as before) and yellow maize meal to 100. Ration 4 was similar but had the extra mineral supplements described for ration 2. All 4 rations were fed to appetite to duplicate per cent. of chicks under constant illumination from The egg for 21 days.

The weight gains on the 4 rations were 226, protein and 219 g., respectively. Serum samples indefinite on the 4 rations gave 2.3, 2.3, 2.7 and the effect per cent. Mg, 2.3, 2.2, 2.5 and 2.5 p.p.m. of animal 1.3, 10.6 and 10.8 mg. per cent. Ca.

Vol. 25, 3, 3

At the end of the trial the right tibiotarsus bone was dissected from each bird, dried, ashed and analysed for Ca. The overall mean dry weight was 840 mg. with 47 per cent. of ash and 17 per cent. of Ca, and the use of molasses had no effect on these values.

It was concluded that the use of molasses, as in this experiment, had no harmful effect on Ca metabolism, despite the slight rise in serum Mg and K.—K. J. Carpenter.

ACKERSON, C. W. and MUSSEHL, F. E. The utilization of food elements by growing chicks. 15. The substitution of Korean lespedeza seed for soybean oil meal in chick rations. *Poultry Sci.*, 1954, **33**, 1228-1229. [Dept. Biochem., Univ. Nebraska, Lincoln.]

A group of 16 chicks was fed from hatching on a 900-g. batch of a pelleted ration made up of soya bean oilmeal 22, meat scraps 5, lucerne meal 2, condensed fish solubles 2, maize gluten meal 10, mineral and vitamin supplements and yellow maize meal to 100, and containing 23.5 per cent. crude protein. The birds ate this quantity of feed in just over 5 weeks and then had a mean liveweight of 453 g.

Two further groups received similar rations with 10 and 20 per cent., respectively, of raw ground Korean lespedeza meal, added in each case at the expense of soya bean oilmeal. Their performance did not differ significantly from that of the birds in the first group.—K. J. Carpenter.

DOW, D. S. and ALLEN, C. E. Rapeseed oil meal in broiler rations with observations on the nature and control of its metabolic inhibitors. *Canad. J. Agric. Sci.*, 1954, **34**, 607-613. [Chem. Div., Sci. Serv., Canada Dept. Agric., Ottawa.]

Chicks fed from hatching to 12 weeks of age on a control ration of soya bean oilmeal 11, fishmeal 8, meat-and-bone meal 8, minerals 0.5, choline, nicotinic acid, vitamins A, B₁₂ and D, sulphaguanoxaline, procaine penicillin, ground wheat 32 and maize meal to 100, finished with a mean weight of 1915 g. Further birds that received an experimental ration of similar composition, but with rapeseed oilmeal in place of soya bean oilmeal, finished with a mean weight of 1868 g., which was not significantly different from that of the control birds. There was no difference in the grading for carcass quality of the birds from the 2 treatments, nor was thyroid function affected by the use of rapeseed meal, so far as could be judged by laboratory tests.

The 2 rations used each contained 3 p.p.m. of iodine, mostly from the fishmeal. Other trials

were made in which higher levels of I were included in rations containing rapeseed meal, but there was no evidence that this had any beneficial effect.—K. J. Carpenter.

4430

JACOBS, R. L., ELAM, J. F., FOWLER, J. and COUCH, J. R. An unidentified chick-growth factor found in litter. *J. Nutrition*, 1954, **54**, 417-426. [Dept. Biochem., Texas Agric. and Mech. Coll. System, College Station.]

Chicks were reared from hatching to 10 weeks of age on a basal ration of soya bean oilmeal 35, mineral supplements 4, riboflavin, nicotinic acid, pantothenic acid, choline chloride, vitamins A, B₁₂ and D₃ and yellow maize to 100. Their mean finishing weight was 1114 g. Others that received the same ration supplemented with 3 per cent. condensed fish solubles weighed 1255 g.

Further groups received the basal ration supplemented with 8 ml. per lb. of an autoclaved "litter extract" that had been prepared by filtering a 35 per cent. aqueous suspension of old poultry litter through cheesecloth and then autoclaving the filtrate for 15 min. at a pressure of 15 lb. per sq. in. These chicks finished with a mean weight of 1308 g. No further stimulation of growth was obtained when fish solubles and "litter extract" were given together. Growth was, however, faster with all treatments when antibiotics were added to the rations as an additional stimulant.

The droppings from the chicks that had had antibiotics showed a lower content of clostridia than those from chicks that had had the basal ration alone. The autoclaved "litter extract" did not have this effect, nor did the extract show antibiotic activity in tests with sensitive micro-organisms.—K. J. Carpenter.

4431

OLLIVERI PETIVA, C. Influenza della lettiera permanente su l'accrescimento e la mortalità dei pulcini. [The effect of deep litter on the growth and mortality of chickens.] *Ann. Sper. agrar.*, 1954, **3**, 1415-1430. [Ist. Zootec. Cascar. Piedmont, Turin.] English summary.

Four groups of White Leghorn chickens were reared on deep litter. For 2 groups the litter was renewed every week. One group in each pair had a ration containing fish and meatmeal, and the other skimmed milk powder. The permanent litter was better for growth, particularly in the group getting skimmed milk, but mortality was higher on the permanent than on the renewed litter.—T. D. Bell.

MORIMOTO, H., YOSHIDA, M., HOSHII, H. and KUBOTA, D. [Nutritive value of wood yeast

for poultry feeding.] *Bull. Nat. Inst. Agric. Sci. Japan* [G], 1954, No. 9, 133-140. In Japanese: English summary.

Wood yeast, *Mycotorula japonica*, when given as 2 per cent. of the diet of laying hens had no effect on egg production or on digestibility of the feed. Normal growth in chickens was obtained when 12 or 20 per cent. of the yeast was incorporated in the ration at the expense of soya bean meal. (From summary.)—J. S. Thomson.

4433

MORIMOTO, H., YOSHIDA, M., HOSHII, H. and KUBOTA, D. [Nutritive value of Koji feed for poultry feeding.] *Bull. Nat. Inst. Agric. Sci., Japan* [G], 1954, No. 9, 125-131. In Japanese: English summary.

Koji feed is a product of the cultivation of *Aspergillus oryzae* on starch pulp, a by-product in the manufacture of starch from sweet potato, with the addition of ammonium sulphate as a source of N. It contains about 11 per cent. crude protein and up to 60 per cent. N-free extract and has a composition similar to that of wheat bran. Chickens grew well when up to 35 per cent. was substituted for cereal brans. With 25 per cent. of Koji feed in the laying ration egg production was good. (From summary).

J. S. Thomson.

4434

HØIE, J. and SANDVIK, Ø. Forsøk med ulike mengder koksalt i føret til kyllinger og høner. [Experiments with different levels of common salt in the rations of chicks and laying hens.] *Meld. Norges Landbrukshøgsk.*, 1954, **34**, 501-524. [Inst. Poultry Fur Animals, Agric. Coll. Norway, Vollebekk.] English summary.

In 1951 a group of white Italian chicks grew slowly, were small at 2 weeks and later unthrifty. They had digestive disturbances and many died. Feathering was slow and the development of secondary sex characters late, so that the sexes could not be distinguished at 4 weeks. Addition of NaCl to the ration, which contained only 0.18 per cent., gave an immediate response.

After this, 7 experiments were made with day-old chicks and 1 with 6-week-old cocks. The chicks had a normal starter meal except that it contained only 0.2 per cent. NaCl, as computed from Na and Cl. Weight increase improved with added salt up to 0.59 and 0.94 per cent. but there may have been retention of water at these levels. The basal diet, containing 0.2 per cent. NaCl, produced pica. In another trial, 4 per cent. salt caused thirst and produced soft droppings but no other evidence of damage. In a third trial 6.2 per cent. salt gave high mortality and oedematous

carcasses, in a fourth, 2.5 per cent. salt gave better weight gain than 0.5 per cent. but 5.5 and 8.5 per cent. were too high.

In 6-week-old chicks given 6.3 per cent. salt appetite was below normal but there was no sign of damage with 4.3 per cent.

Two further trials showed that deficiency of NaCl is deficiency of Na, not of Cl nor of both, and that the higher percentages of NaCl do reduce the dry matter of carcasses.

The final trial was with 6 groups each of 2 laying hens. Salt in feed varied from 0.5 to 6.5 per cent. Most eggs were laid at 3.5 per cent. At all levels above 0.5 per cent. droppings were soft and water consumption was high.—I. Leitch.

4435

MORRISON, M. A., SAUTER, E. A., McLAREN, B. A. and STADELMAN, W. J. **Some factors affecting yield and acceptability of chicken broilers.** *Poultry Sci.*, 1954, **33**, 1122-1125. [Washington Agric. Exp. Stat., Pullman.]

Sample 12-week-old broilers from 8 different breeds or crosses were killed, dressed, eviscerated and autoclaved to allow separation of meat and bone. The mean eviscerated weight was 80.5 per cent. of the dressed weight, and edible meat formed 68.5 per cent. of the eviscerated carcass. There was no difference between the different types of birds examined.

Further birds were roasted and examined for tenderness and flavour by a consumer panel. Tenderness was also measured mechanically in terms of the force needed to shear a 1-cm. square of flesh. Again there was no significant difference between the types of birds examined.

EGG PRODUCTION

4437

GRIMINGER, P. and SCOTT, H. M. **The effect of different cereals on feed efficiency, egg quality and shell thickness.** *Poultry Sci.*, 1954, **33**, 1217-1219. [Illinois Agric. Exp. Stat., Urbana.]

Four groups, each of 17 to 20 White Leghorn pullets, were fed in a reversal type of trial, in which they received 4 experimental rations in successive 3-week periods. In each ration 27.5 parts were made up of soya bean oilmeal 16, lucerne meal 5 and mineral, vitamin and antibiotic supplements. The remainder of the ration consisted of yellow

maize meal, ground oats, ground wheat, or a mixture of the cereals.

In the second and third weeks of each period the weights of eggs produced on the different diets were 73, 41, 79 and 72 lb., respectively. The quantities of each ration eaten were similar, being 250, 251, 268 and 264 lb., respectively, but these corresponded to calculated productive energy intakes of 235, 166, 228 and 217 lb., respectively. The low egg production on the oat ration was therefore associated with a lower intake of productive energy. The birds also lost weight while on this ration.

There was no detectable effect of diet on quality, shell thickness or weight of the eggs laid.

K. J. Carpenter.

4438

MANTEL, K. Einfluss von verschiedenen hohem Getreideanteil im Mischfutter auf Legeleistung, Züchterfolg und Wirtschaftlichkeit der Fütterung. [Effect of different levels of grains in a mixed ration on egg yield, breeding and economics of feeding.] *Arch. Geflügelk.*, 1954, **18**, 428-437. [Geflügelzüchtelanst. Erding, Obb.] English summary.

A preliminary experiment with laying hens, which is described, suggested that feed utilisation was best when the percentage of grain in the total ration was highest. Since, however, the rations differed widely, another experiment, over 350 days, was made with 4 groups each of 30 Leghorn and 30 Italian pullets. All groups had 20 g. oats in the morning and 30 g. mixed wheat and barley at night and a wet mash at mid-day. The basal mash was wheat bran 25, wheatmeal 25, Maizena 15, meatmeal 8, herringmeal 5, dried milk 2, dried yeast 2, linseed meal 5, lucerne meal 6, sugar beet shreds 5 and Vitakalk 2 per cent. The experimental groups had 15, 30 or 50 per cent. ground grain (barley and oats) and less bran, wheatmeal and Maizena. The Leghorns, but not the Italians, had artificial lighting to give a 12-hr. day in winter.

Feed intake, number of eggs produced, egg weight and efficiency of feed utilisation rose steadily with increase of the proportion of grain in the ration, with both breeds. The Leghorns did better than the Italians. The number of eggs produced in winter also rose, and the respective costs of production per 100 g. egg were 20.0, 18.8, 19.0 and 16.8 Pf. Moreover, the groups receiving more grain included more birds fulfilling the conditions for recording (175 eggs of at least 55 g.). Hence a laying mash containing 50 per cent. ground grain is recommended both for breeding and for egg production.—W. M. Deans.

4439

DYMSZA, H., BOUCHER, R. V. and MCCARTNEY, M. G. **Influence of dietary fiber and energy**

levels on reproductive performance of turkey pullets. *Poultry Sci.*, 1954, **33**, 1159-1163. [Dept. Agric. Chem., Pennsylvania State Univ., State College.]

Four groups, each of 20 turkey pullets, in colony houses with outside porches were inseminated artificially at 3-week intervals and trap-nested, and the eggs were incubated. Each group received a different ration. Ration 1 was of fishmeal 5, dried brewer's yeast 3, dried whey 2, soya bean oil meal 8.5, choline chloride 0.05, mineral and vitamin supplements 5.3, ground oat hulls 6.5 and yellow maize meal to 100. Rations 2, 3 and 4 were of similar composition but contained 23.8, 40.8 and 58 per cent., respectively, of oat hulls and 11, 13.5 and 16 per cent. of soya bean oilmeal. These 4 rations were calculated to contain 5, 10, 15 and 20 per cent. of crude fibre and 882, 670, 460 and 249 Cal. per lb. of productive energy, respectively.

In 84 days each group had a mean production of 48 eggs per head, but feed consumption was greater with the rations of lower energy content so that for rations 1 to 4 the feed conversion efficiencies (lb. feed per dozen eggs) were 11.1, 13.3, 16.3 and 21.7, respectively.

Approximately 50 per cent. of the eggs from each group proved to be fertile. Of fertile eggs the proportions hatching were 61, 49, 44 and 21 per cent. for the birds receiving rations 1 to 4, respectively.

It is concluded that although turkeys may be able to increase their consumption of a low-energy diet so that egg production is unaffected, such a ration may still be unsuitable if the eggs are to be used for hatching.—K. J. Carpenter.

4440

SKALLA, E. Der Einfluss der Fütterung auf die jahreszeitliche Verteilung der Eierproduktion. [Effect of feeding on the seasonal incidence of egg laying.] *Arch. Geflügelk.*, 1954, **18**, 327-339. [Inst. Tierzucht., Landw. Hochsch., Hohenheim.] English summary.

In this extract from a thesis, data for White Leghorn and partridge-coloured Italian hens, 1756 in all, in their first laying year in 1937-38, 1946-47 and 1948-49 are compared. All were reared at the Institute and the environment was constant, but the rations differed in composition: animal protein 7.04, vegetable protein 10.01, N-free extract 56.75, ballast 27.29 g., per hen daily in 1937-38, corresponding figures for the later periods being 3.29, 6.16, 39.14, 30.30 and 4.48, 12.85, 57.75, 26.82.

The effects on egg production are illustrated by diagrams for White Leghorns hatched in March. Annual egg production, 200 per bird in 1937-38, fell to 116.2 with the inadequate feeding of

1946-47, but rose again to 175.9 in 1948-49. The fall in winter egg production was particularly marked and there was a tendency for the natural laying cycle to re-assert itself. Those hatched in April showed an even greater fall in winter egg production. The results indicate that March hatching is desirable when feed is scanty, April hatching when it is plentiful. Individual variations were much more marked in 1946-47, except during the natural laying period; hence for selection for winter egg production, a scanty ration is recommended. Comparison of flocks for winter egg production is futile unless the feeding is the same. The Italians showed similar effects; their lower total egg production was due to lower production in winter and their egg production was more affected by adverse conditions than that of the Leghorns, but on the other hand more of the Leghorns died.

In the Italians, but not in the Leghorns, egg weight was reduced by poor feeding; it was concluded that egg weight depends primarily on genetics and only secondarily on feeding.

W. M. Deans.

4441

ARSCOTT, G. H., SWEET, G. B. and COMBS, G. F. Effect of iodinated casein in a simplified oat diet on hatchability of chicken eggs. *Poultry Sci.*, 1954, **33**, 1283-1286. [Dept. Poultry Husb., Univ. Maryland, College Park.]

For 6 weeks pullets, housed in wire-floored pens, were fed on a ration (1) made up of oat groats 93.5, DL-methionine 0.08, mineral supplements, vitamins A and D feeding oil and all the known vitamins. The 200 birds were then divided into 4 groups.

In the next 16 weeks group 1, which continued to receive the same ration, gave eggs from which, on incubation, 86 per cent. of the fertile hatched. Groups 2, 3 and 4 received the same ration supplemented with 3 per cent. condensed fish solubles, additional vitamins or additional vitamins plus 0.0135 per cent. of a xanthophyll concentrate; the corresponding hatchability figures were 80, 83 and 83 per cent.

Over a further period of 8 weeks groups 1 and 2 gave fertile eggs with hatchabilities of 78 and 84 per cent., respectively. Group 3 was changed to ration 1 with a supplement of 50 mg. iodinated casein per lb., and gave fertile eggs with 58 per cent. hatchability. Group 4 received ration 1 supplemented with 5 µg. procaine penicillin G and 10 mg. chlortetracycline per lb. and gave fertile eggs with 85 per cent. hatchability.

It is concluded that the rations used were unsuitable for the study of "unidentified factors" necessary for hatchability, although the requirement for these might have been raised by the feeding of iodinated casein.—K. J. Carpenter.

N.A. and R., July 1955

4442

O'ROURKE, W. F., BIRD, H. R., PHILLIPS, P. H. and CRAVENS, W. W. The effect of low phosphorus rations on egg production and hatchability. *Poultry Sci.*, 1954, **33**, 1117-1122. [Dept. Poultry Husb., Univ. Wisconsin, Madison.]

White Leghorn pullets that had been laying for a month and had shown a high rate of production were placed in individual cages and given an experimental mash, oyster shell grit and water to appetite; they were inseminated artificially at weekly intervals.

All the birds received a basal ration of soya bean oilmeal 19, maize gluten meal 16, methionine 1, soya bean oil 1.5, NaCl 0.25, vitamins and sucrose to 100. Supplements of $\text{CaHPO}_4 \cdot 2\text{H}_2\text{O}$ were given so that the 5 rations had contents of P ranging from 0.19 to 0.60 per cent.

In 12 weeks egg production, and hatchability of eggs, of birds receiving only 0.19 per cent. P in their ration declined greatly, but were maintained in groups receiving 0.3 to 0.6 per cent. P. For the next 6 weeks the birds receiving low-P rations were given higher levels, and vice versa, and their performance also changed accordingly. Most of the embryos failing to hatch in the low-P group died in the second week of incubation.

In the ration containing 0.3 per cent. total P, the non-phytin fraction was 0.18 per cent. and this appeared to be adequate for normal reproduction.—K. J. Carpenter.

4443

CHOMYSZYŃ, M. Wpływ paszy na jakość tłuszczu u gęsi. [The influence of feed on the quality of fat in geese.] *Roczn. Nauk rol.* [B], 1954, **69**, 91-104. Russian and English summaries.

Twenty-eight geese were given barley only for 12 days, then an addition of 40 ml. rapeseed oil daily for another 16 days and finally barley only for another 12 days. At the beginning of the rapeseed oil period, every 4 days during and at the end of the period, 4 geese were killed. When back on the exclusively barley ration 4 geese were killed after 8 days and 4 after 12 days. From all slaughtered birds samples of subcutaneous and internal (mesenteric and peritoneal) fat were tested for iodine value, saponification value, refractive index and melting-point.

Both subcutaneous and internal fat assumed the qualities of rapeseed oil in all characteristics tested and in consistency and smell when rapeseed oil was given. The changes were distinct only after 8 days on the oil diet, and disappeared after 8 days when oil was not given. Subcutaneous fat was softer than internal, having higher I value and refractive index and lower melting-point, whether oil was given or not. (From summary.)—T. D. Bell.

4444

BIELY, J., MARCH, B. E. and SILVESTRI, D. A. Fat studies in poultry. 1. Herring oil, Santomerse-80 and thyroprotein in the laying ration. *Poultry Sci.*, 1954, **33**, 1130-1135. [Poultry Nutrit. Lab., Univ. British Columbia, Vancouver.]

Twenty-six White Leghorn pullets were housed in individual cages and fed from 6 to 17 months of age on a ration (1) of herringmeal 2.75, soya bean oilmeal 14, dried maize fermentation solubles 1, choline chloride 0.06, minerals 6.5, feeding oil 0.5, bran 5, yellow maize meal 10, ground barley 10, ground oats 10, maize starch 6 and ground wheat to 100. A second set of birds received a similar ration (2), but with 6 per cent. of herring oil replacing the maize starch of ration 1. On a hen-day basis the mean egg-production on rations 1 and 2 was 61.3 and 63.6 per cent., respectively, with feed conversions of 5.37 and 4.75 lb. of feed consumed per dozen eggs.

Further groups received rations 1 and 2 each supplemented with 0.1 per cent. of "Santomerse-80" (an alkyl aryl sulphonate used as a surface-active agent), and they gave 63.1 and 61.6 per cent. production with feed conversions of 5.10 and 4.67, respectively. Finally, groups that received rations 1 and 2 supplemented with 150 mg. iodinated casein per lb. gave 53.5 and 56.9 per cent. production, and used, respectively, 6.02 and 5.46 lb. of feed per dozen eggs laid.

On each of the 6 rations 6, 7 or 8 of the birds died during the pullet year. The birds that received ration 1 supplemented with iodinated casein showed a mean liveweight gain of 0.4 lb. over the experiment, those that received ration 2 with the same supplement gained 0.7 lb. The groups receiving rations 1 and 2 unsupplemented gained 0.9 and 0.8 lb., respectively.

It is concluded that 6 per cent. of herring oil may be included in a laying ration without adverse effect and with some improvement in feed conversion efficiency. This improvement may be enhanced by the feeding in addition of a surface-active agent, which may act by allowing more efficient absorption of fat from the intestine.

GAWĘCKI, K. and PONIKIEWSKA, T. Naświetlano drożdże pastewne w jesienno-zimowym żywieniu kur niosek. [Irradiated fodder yeast in the autumn and winter feeding of laying hens.] *Roczn. Nauk rol.* [B], 1954, **68**, 253-270. Russian and English summaries.

Fodder yeast as 10 per cent. of the ration was given during the autumn and winter to 2 groups of laying White Leghorns and Rhode Island Reds, one group having half of its yeast irradiated. No

difference between groups was found in health, egg production or chemical composition of the egg shells. It is concluded that under Polish conditions when 10 per cent. fodder yeast is included in the ration the addition of cod liver oil is unnecessary. (From summary.)

J. S. Thomson.

4446

GAWECKI, K., NEUMAN, M. and PONIKIEWSKA, T. Wpływ drożdży nasłiwianych na wylęgowość jaj kur różnych ras. [The influence of irradiated yeast on the hatchability of eggs of hens of different breeds.] *Rocz. Nauk rol.* [B], 1954, 68, 475-488. Russian and English summaries.

Yeast comprised 5 per cent. of the mash of 104 Rhode Island Red and 268 Leghorn hens. In the ration of half of the hens half of the yeast was irradiated. In 3 months the birds receiving irradiated yeast hatched 3044 eggs, compared with 2906 for the controls. This represented an increase of 4 per cent. in the Rhode Island Reds and 9 per cent. in the Leghorns. No influence of irradiated yeast on fertility was observed. (From summary.)

MOORE, E. N., CHAMBERLIN, V. D. and CARTER, R. D. Safety of arsenic acid for turkey breeders. *Poultry Sci.*, 1954, 33, 1115-1116. [Ohio Agric. Exp. Stat., Wooster.]

A group of 36 breeding turkeys was fed for 2 weeks on a commercial ration supplemented with 900 g. arsenic acid (*p*-aminophenylarsonic acid) per ton, and for a further 3 weeks with a supplement of 100 g. per ton. A control group received the same commercial ration with no supplement.

In the 5 weeks of the trial the control group gave 64, 68, 54, 41 and 47 per cent. production; the corresponding figures for the supplemented group were 49, 31, 16, 33 and 55 per cent. The hatchability of the fertile eggs from the control group in the first 4 weeks was 61, 72, 74 and 58 per cent., respectively; the corresponding figures for the supplemented birds were 59, 26, 41 and 58 per cent. The general appearance of the supplemented group and the fertility of their eggs were not obviously affected.

It is concluded that turkeys can tolerate a high dose of arsenic acid for short periods, but that it can be expected that egg production and hatchability will be adversely affected.—K. J. Carpenter.

4449

SWART, L. G. Feeding systems for laying hens. *Farming in S. Africa*, 1954, 29, 542-543; 548. [Stellenbosch-Elsenburg Coll. Agric., Stellenbosch.]

Three different systems of feeding were tested for their effects on egg production, namely, mash plus scratch grain, all-mash, and mash and grain to appetite. There was little effect on egg production. Feed consumption was highest on the all-mash ration; in the other 2 groups consumption of grain was higher than that of mash. Mortality was somewhat higher in the group getting mash and grain to appetite.—J. S. Thomson.

OTHER BIRDS

mash of soya bean meal 30, fishmeal 5, meat scrap 5, dried skimmed milk 5, dried distiller's solubles 5, minerals 3, fish liver oil 1, ground oats 10, standard middlings 18 and maize meal to 100. The birds grew well and had a mean weight of approximately 270 g. at 5 weeks of age, but they showed a high incidence of feather picking.

Equally rapid growth was obtained with similar rations containing higher levels of ground oats, or with the inclusion of 10 or 20 per cent. oat hulls, and they appeared to discourage feather picking. Under these conditions growth was not slowed significantly if the level of soya bean meal was

N.A. and R., July 1955

reduced to 18 per cent., so that the total crude protein content of the rations was reduced from 28 to 24 per cent. When very coarsely ground oat hulls were used the birds picked these out of the feed troughs preferentially, and growth rate was then depressed.

3. In further trials the basal ration used was of soya bean meal 36.5, fishmeal 10, dried yeast 5, dried whey 5, lucerne meal 3, minerals 3, nicotinic acid, middlings 12.5, ground oats 10 and maize-meal to 100, and the pheasant chicks were reared in pens on floors covered with wood shavings. At 6 weeks of age chicks receiving this ration had a mean weight of 290 g.; others receiving the same mash supplemented with 22 p.p.m. terramycin were 18 per cent. heavier and had a lower death rate. Tests with bacitracin, procaine penicillin and aureomycin indicated that they also stimulated growth to about the same extent, but the use of antibiotics had no effect on the high incidence of feather picking that occurred in these trials. The use of 440 mg. iodinated casein, or 88 mg. 3-nitro-

4-hydroxyphenylarsonic acid per kg. as supplements to rations in addition to aureomycin also failed to reduce its incidence.—K. J. Carpenter.

4451

BALDINI, J. T., ROBERTS, R. E. and KIRKPATRICK, C. M. The reproductive capacity of bobwhite quail under light stimulation. *Poultry Sci.*, 1954, **33**, 1282-1283. [Purdue Agric. Exp. Stat., Lafayette, Ind.]

Three hens and one cock from a hatch of Bobwhite quail chicks were given continuous lighting in an indoor cage and fed on a standard poultry mash. One bird began to lay at 172 days of age and in the following 224 days the females had a mean production of 170 eggs per head.

As the birds were not of a specially selected strain it is considered that with improved diet, environment and management quails are capable of laying considerably more than the 70 eggs per season which is considered a good standard at present.—K. J. Carpenter.

LEWIS, J. N. and SAXON, E. A. Agricultural output requirements for future population growth in Australia. *Quart. Rev. Agric. Econ.*, 1954, **7**, 151-155.

Vol. 25, No. 3

It is estimated that even with no net immigration the population of Australia will reach 10.9 million by 1976, or with a net immigration of 100,000 a year, 13.9 million. Estimates of the corresponding production requirements for the main agricultural commodities, to cover home needs, present exports, and increased exports of wool, wheat and flour, mutton and lamb, and beef and veal to pay for the additional imports necessary, are given in a table along with production figures for 1952-53. These estimates are based on figures for present and past annual consumptions per head, which are tabulated for 1951-52 and periods in the 3 preceding decades, with certain assumptions about future changes in consumption and general economic conditions. In the aggregate, agricultural production will have to be expanded by 27 per cent. from the 1952-53 level, which itself is 20.5 per cent. above the pre-war one, or by 56 per cent. for the larger population estimate. For the latter, a rate of expansion of about 2 per cent. per annum would be required. This is within the limits of Australia's physical resources, but will demand a vigorous agricultural policy.—W. M. Deans.

CAMPBELL, D. R. Neo-malthusianism. Its origin, decline and recent renaissance. *Agric. Inst. Rev., Canada*, 1955, **10**, 13-15; 50-51. [Dept. Agric. Econ., Ontario Agric. Coll., Guelph.]

Population growth and food production are discussed with particular reference to Canada.

Population is growing at the rate of about 2.6 per cent. per annum but food production at the rate of 3.1 per cent. The possibilities of still higher production are excellent. Only a small fraction of land receives fertiliser each year and much less is irrigated. Improvements in plant and animal breeding and in farm management will speed production. Indeed, in Canada, the chief worry is surpluses and neo-malthusian arguments have little place and little appeal.—I. Leitch.

DE JONG, W. **Veeteelt in Nieuw-Guinea.** [*Animal husbandry in New Guinea.*] *Landbouwk. Tijdschr.*, 1954, (Nieuw-Guinea No.), 67-71. [Landbouwhogeschool, Wageningen.] English summary.

The stock population is assessed as about 1 thousand cattle, 500 to 600 horses, 500 pigs in Europeans' herds and some thousand belonging to the indigenous people, 2 to 2.5 thousand goats and not more than 100 sheep. There are 30 to 40 thousand poultry not including an unknown number in indigenous flocks. There is no likelihood of expansion without planning, the development of forage crops and the import of breeding stock. Fishing should be developed as an independent source of food and an incidental source of animal feed.—I. Leitch.

4462

EDWARDS, J. **Scientific trends in milk production in Great Britain.** *Vet. Rec.*, 1955, 67, 2-12 (with discussion 13-14). [Prod. Div., Milk Marketing Board.]

In the introduction the major changes in the milk production industry during the years 1939 to 1953 are discussed. It is shown that the weekly

consumption of liquid milk in Great Britain per head rose from 3 pints in 1939 to 5 pints in 1953. In England and Wales the amount of milk sold for liquid consumption increased from 760 million gal. in 1939 to 1342 million in 1953. Milk sold for manufacturing purposes fell from 363 million gal. in 1939 to 130 million in 1943 and rose to 293 million in 1953. The changes in Scotland over the same period followed a similar pattern. Future trends in milk production are discussed under the headings of breeding, management and disease control.

With regard to breeding it is shown that the proportion of cattle bred by artificial insemination in England and Wales is now (September 1954) 43.8 per cent. One of the main contributions of artificial insemination to increased productivity is considered to be the ease with which breed changes may be effected. It is estimated that 25 per cent. of the increase in yield over the past 10 years is due to change of breed. The possible benefits to be derived from the use of artificial insemination are discussed in the light of modern genetic theory. It is shown that estimates of the breeding value of a bull based on the yields of his daughters are of limited value, since the yields themselves depend on the management of the herd. The use of artificial insemination coupled with improvements in management would lead to greatly increased productivity.

In the field of animal health the author confines himself to a study of the problem of infertility in dairy herds and emphasises the seriousness of temporary infertility, but concludes on the whole that the cow is a member of a very fertile species.

CLARK, J. and BESSELL, J. E. **Progress in milk production. A study of forty farms 1949 to 1952.** *Imperial Chemical Industries, Ltd., London, Agric. Development Dept. Bull.* No. 5, May 1954, pp. 91.

Higher and more economically efficient milk production has been obtained from greater reliance on, and better utilisation of, grassland, less feed being purchased. Thus the proportion of starch equivalent in the cow's ration provided by grazing and conserved grass increased from 55 per cent. in 1949 to 63 per cent. in 1952, and milk production per cow-feed acre (area of homegrown feeds plus the estimated acreage equivalent of purchased feeds, excluding the requirements of replacement stock) increased over this period from 207 to 239 gal., giving a higher profit per acre from the dairy herd. From the practical point of view an increase in production per acre is more easily achieved by increasing the density of stocking than by increasing the average herd yield, though this is an important long-term supplementary aim.

N.A. and R., July 1955

Statistical analyses of the data show that reducing feed-area requirement by $\frac{1}{2}$ acre per cow gives a milk yield increase of 45 gal. per acre; an increase of 16 gal. per acre is obtained from raising yield by 100 gal. per cow. With each additional 1 cwt. sulphate of ammonia up to 3 applied per acre of grassland there was an associated average increment of 22 gal. milk per acre, though this probably arose to a considerable extent from concomitant improvements in pasture management.—J. L. Corbett.

MINISTRY OF AGRICULTURE AND FISHERIES (with UNIVERSITY OF NOTTINGHAM). Costs and efficiency of pig production. A comparison between England and Denmark. H.M.S.O., London, 1954, pp. iv + 45. Price 2s. net.

Large government subsidies are paid to British pig producers, and under completely free market conditions these producers would be at a considerable disadvantage unless they were able to bring their production costs down in line with those of

their Danish competitors. This publication attempts to establish why Danes can sell bacon more cheaply, and to suggest ways in which the British producers could increase efficiency.

During 1949-53 England had 100 per cent. more boars than Denmark and 25 per cent. more breeding sows and gilts, but only 15 per cent. more suckling and weaned pigs. In England and Denmark the numbers of pigs reared to slaughter per sow per year were 12.2 and 15.5, respectively. This difference in breeding herd productivity is accounted for by a lower number of farrowings per sow per year in England (1.8 against 2.0) and by a smaller number of pigs born and weaned per litter in England (9.4 and 7.4 against 10.7 and 8.3).

At costs prevailing in the last quarter of 1953 Danes produced bacon pigs at less than two-thirds of the costs of English production. The largest difference was in feed costs and was attributable to higher efficiency of feed conversion and lower feed prices in Denmark. In England it took 8.56 lb. meal per lb. liveweight increase to produce a 32-lb. weaner, this figure including the "overhead" of a proportion of the feed eaten by the sow. The comparable figure in Denmark was 5.70. During the fattening period it took 4.72 and 4.31 lb. meal per lb. liveweight increase in England and Denmark, respectively. Despite these figures, differences in prices of feedingstuffs accounted for almost two-thirds of the difference in feeding costs between the 2 countries.

Important contributions to the efficiency of Danish pig production are the establishment of élite herds, the progeny testing of both national and local élite herds, the publication of all results from the progeny tests and the large numbers of boars sold from élite herds. The average total boar population in Denmark is about 12,000 and the annual sale of boars from élite herds is over 8000.

A method of financing and establishing an élite herd and progeny testing system in Britain is suggested.

Details are given of costing systems and the methods of obtaining the data used. There is also a brief outline of the place of pig production in the agriculture of the two countries.

I. A. M. Lucas.

HEIDA, J. Enkele gedachten over de organisatie van de varkenshouderij in Nederland. [The organisation of pigkeeping in the Netherlands.] *Tijdschr. Diergeneesk.*, 1955, 80, 261-263. [Beetsterzwaag.]

In 1954 about 4 million pigs were slaughtered in the Netherlands, one-tenth of them by self-suppliers. There were also 300,000 breeding sows. Of the 4 to 5 million pigs farrowed, it is reckoned that about 20 per cent. are lost. The value of the

pigs slaughtered is about 800 million gulden, compared with 400 million from poultry and about 1400 million from cattle.

The need for research into pig diseases and education in feeding and management is briefly discussed.—I. Leitch.

4470

NELSON, M. *Sheep farming in Waipukurau County, Hawkes Bay. Canterbury Agric. Coll. Tech. Publ. No. 10, October 1953, pp. 28.* [Lincoln Coll., Christchurch.]

An exhaustive survey of sheep farming conditions, management and production in the area is reported. It was found that the greater the carrying capacity of the land, the smaller was the farm and the less the production per unit of labour and per ewe-equivalent. Production per acre increased and more artificial fertiliser was used and more fodder crops were grown on the farms with higher carrying capacity.

The conditions ruling the type of management and the standard of production are discussed. Suggestions for increased production are made, and limitations existing are noted.—T. D. Bell.

carne en Puerto Rico. [The cost of production of poultry for meat in Puerto Rico.] Univ. Puerto Rico Agric. Exp. Stat. Bull. No. 117, January 1954, pp. 21. [Río Piedras, Puerto Rico.] English summary.

An economic study of broiler production was made on 13 poultry farms in Puerto Rico, including large (over 20,000 broilers per year), medium (10,000 to 20,000) and small (up to 10,000) units. Average feed consumption to the broiler stage, 2½ to 2½ lb. weight, was 8.6 lb., ranging from 9.8 lb. on the large farms to 7.3 or 7.4 lb. on the medium and small units, and average feed consumption per lb. meat was 3.6 lb., with a range from 3.2 to 3.9 lb. Average gross return per 1000 broilers was \$1217 and average expenditure \$991, including \$517 on feed, so that net return per 1000 broilers was \$226. (From summary).—J. S. Thomson.

DIET IN ETIOLOGY OF DISEASE

GENERAL

4479

SCHÜRMANN, E. and MÜLLER, R. *Zum Fragenkomplex der unspezifischen Sterilität des Rindes. 1. Grundsätzliches zu einem Forschungsvorhaben. [The problem of non-specific sterility in cattle. 1. The basis of a plan of research.]*

MÜLLER, R. and HÖHN, E. *2. Der Einfluss von Witterungsfaktoren auf die Fruchtbarkeit des Rindes. [2. The effect of weather on fertility in cattle.] Ztschr. Tierzücht. Züchtungsbiol., 1954, 64, 85-90; 91-102.* [Inst. Anat. Physiol. Haustiere, Univ. Bonn.]

1. This introduces a series of reports on an inquiry asked for by the Minister of Food,

N.A. and R., July 1955

Agriculture and Forestry of Nordrhein-Westfalen in 1952.

Disturbances of fertility caused by specific disease have increasingly come under control, but non-specific sterility has no clinically recognisable sign and may arise from different causes. Heredity may be involved, or external environment. So far heredity has received little attention in this context, yet selective breeding has produced earlier maturity and more frequent oestrus; at the same time it has failed to increase resistance to unfavourable circumstances.

Of environment the most important component is feed, and the proper balance and use of feed still require a great deal of further investigation. There may be a delicate balance between diet and hormone balance, or it may be more important to study constitution. The present study is an attempt to record environment and to analyse its components in relation to non-specific sterility.

2. Literature is reviewed. The area studied, the Rhein-Bergischer Kreis, has a large artificial insemination centre and was otherwise chosen for its relatively simple and uniform feeding conditions. It is a farming area, mostly with small units of 5 to 15 hectares, on rolling or hilly country, devoted chiefly to dairy farming. The cattle are pastured all summer and autumn with extra clover or grass at the height of summer and beet leaves in autumn. Winter feed is hay and concentrates with little silage. The cows are black-and-white or occasionally red-and-white Niederungsvieh (Lowland breed). The meteorological data were collected from the local agricultural school and covered the years 1951 and 1952.

Disturbance of reproduction was measured by the proportion failing to conceive at first service (*Umrinderungsquote*). In accordance with general custom this index is plotted against month. Fluctuations were large. Taking both years together, results were possibly best in May. There was little effect of temperature in either year; fertility varied inversely with rainfall, but the closest correlation was with barometric pressure and the index rose and fell with it in both years.—I. Leitch.

4480

FOSTER, A. H. An emaciation syndrome in **Malayan cattle**. *Vet. Rec.*, 1955, **67**, 167-168; 169. [Vet. Div., Dept. Commerce and Indust., Singapore.]

Cows which had died showing an emaciation syndrome frequently seen in crossbred Zebu cattle in Malaya were examined. The livers were paler than normal, and friable, and the condition was described as "degenerative fatty infiltration". The pancreas was infested with *Eurytrema pancreaticum* flukes. The diet of the cattle had been

deficient in bulk; the grass they got was very low in protein and they had been given disproportionate amounts of concentrates. The similarity of the pathology to dietary diffuse hepatic fibrosis in rats, dogs and man, and the effects of pancreas removal on dogs, are discussed.—T. D. Bell.

4481

NEWBOLD, R. P. Preliminary note on the extraction of a bloat-promoting fraction from red clover. *N.Z. J. Sci. Technol.* [4], 1954, **36**, 285-286. [Grasslands Div., D.S.I.R., Palmerston North.]

The vacuolar fluid expressed from red clover plants, including stem and leaf, caused bloat when from 16 to 18 litres were given as a drench to dry dairy cows. The press cake with similar volumes of water or glucose solution had no deleterious effect. It is suggested that the substance causing bloat should be sought in the vacuolar fluid.

T. D. Bell.

4482

WHITE, W. J., GREENSHIELDS, J. E. R. and CHUBATY, W. The effect of feeding sweet clover silage on the prothrombin time of blood of cattle. *Canad. J. Agric. Sci.*, 1954, **34**, 601-606. [Dominion Forage Crops Lab., Saskatoon, Sask.]

Six herds were used, 3 on sweet clover silage and 3 on hay, chiefly alfalfa. After 8 to 10 weeks 2 of the silage group showed significantly higher prothrombin times than the third, for which values were normal. In both the affected herds the silage was mostly of inferior quality, being mouldy or dark brown from the outer edges of the silo; in the unaffected group the silage was dark green and of good quality from the interior of the silo. Stage of lactation or exposure to cold did not affect prothrombin time. Chemical analyses of the mouldy and dark brown silage showed the presence of dicoumarol.—J. S. Thomson.

4483

DALE, D. G. and CRAMPTON, E. W. Observations on chronic fluorosis in dairy cattle. *Canad. J. Comp. Med.*, 1955, **19**, 6-16. [Dept. Animal Pathol., Macdonald Coll., Que.]

Fluorine metabolism and the pathology and signs of chronic fluorosis are discussed. Three herds affected to different degrees by chronic fluorosis are described. The source of the fluorine was thought to be raw rock phosphate which had been used as a source of Ca and P in the mineral mixture. The widespread occurrence of chronic fluorosis in Canada is discussed; another possible cause in some areas is industrial contamination of pastures and grains.—T. D. Bell.

4484

FITCH, L. W. N. Osteodystrophic diseases of sheep in New Zealand. 2. "Bowie" or "bent-leg". *N.Z. Vet. J.*, 1954, 2, 118-122. [Animal Res. Stat., Dept. Agric., Wallaceville, N.Z.]

Bowie occurs in restricted areas distributed in 6 counties of the South Island, but has not been reported in the North Island. It has been known for some 50 years. The incidence varies from year to year, but is not known to be correlated with climatic conditions. Several breeds of sheep are affected.

Tenderness of the feet and a tendency for the legs to bend may be seen in lambs 3 or 4 weeks old, and by 6 or 8 weeks of age the fore legs are bandy, with toes turned in and elbows pushed out. The hind legs may or may not be affected. Sometimes the knees turn in instead of out. Some, but not all, of the affected lambs are lame, and all are usually unthrifty.

Macroscopically, the long bones appear to be well developed and not porotic. The epiphyseal cartilages may be greatly thickened in parts. There is no obviously rachitic metaphysis. The joints may contain much fluid, and articular surfaces may be eroded. In early stages the synovial membrane is congested, and in chronic cases there may be much thickening of the joint capsule.

As in rickets, the most striking histological feature is the persistence of mature cartilage cells at sites of endochondral ossification, but in contrast to rickets, no gross failure of provisional calcification has been found. The depth and extent of cartilage calcification is unusually variable and sometimes seems excessive. There is no osteoporosis and long bones are heavy and dense. Osteoid tissue, common in rickets, is absent in bowie. The metaphyseal lesion differs from that of rickets.

Blood Ca and P in samples from bowie lambs were within normal limits.

The clinical condition of the lambs and the histology of the lesions are shown in photographs. D. Duncan.

DEFICIENCY DISEASES

4487

EISMA, W. A., HOSKAM, E. G., DORSMAN, W. and WIERINGA, G. W. Enige waarnemingen over het zogenaamde kopergebrek bij runderen. [Some observations on so-called copper deficiency in cattle.] *Tijdschr. Diergeneesk.*, 1955, 80, 247-255. [Lab. Rijksseruminrichting.] English, French and German summaries.

Within recent years complaints have increased in frequency from farms on moor and fen of poor condition in cattle, with rough coats, brown or white depigmentation of black hair, low milk production and diarrhoea. On current accepted standards, blood Cu is usually low. Pasture Cu is normal, over 7 mg. per kg., and administration of CuSO_4 , up to 500 mg. per head daily, produces little or no benefit. This is in contrast to sand areas, where there is a real deficiency in soil and pasture and CuSO_4 gives direct response.

The Mo content of Netherlands soils is low. Wind and Deys (*Landbouwk. Tijdschr.*, 1952, 64, 23) are quoted for the view that the ratio of total base : total acid in pasture determines Cu requirement. A ratio of 1 means a requirement of 15 mg. Cu per kg. grass; with a ratio of 1.3, 11 mg. is enough. Other complications are quoted.

Claims to have deficiency of Cu were investigated on 4 farms. On the first there was depigmentation, young cattle were slow to breed and milk yield was low. Infestation with lung worms and *Trichostrongyles* was severe. Blood Cu in 29 cows was on the average 18 μg . per cent.; grass had 17.0, hay 11.1 and grassmeal 11.4 mg. per kg. CuSO_4 was given in the drinking water. Six young animals of average weight 200 kg. were moved to the Rijksseruminrichting (State Serum Institute) and fed, one group of 3 on hay and green feed from the farm, the other on Serum Institute hay with only 7.8 mg. Cu per kg., concentrates, salt and vitamin D. In both groups serum Cu rose. Later complaints disappeared when the manager changed and the cattle were given relatively more concentrates.

On a second farm there was depigmentation in cows and low milk yield. A supplement of 0.5 g. CuSO_4 and 5 mg. CoSO_4 per cow daily raised the average milk yield from 9 to 24 litres daily and blood Cu from 56 to 84, 33 to 65 and 63 to 77 μg . per cent. When the Cu supplement was omitted, milk yield fell. This is regarded as a farm with genuine deficiency. The vitamin B_{12} content of faeces was not affected by the Co supplement.

On 2 other farms, much the same signs, occurring on one in spite of giving 1 kg. concentrates, 1 g. CuSO_4 and about 5 mg. CoSO_4 per head daily, are attributed to heavy infestation with *Trichostrongyles*.

N.A. and B., July 1955

gyles. Serum Cu varied on the first of these farms between 45 and 82 μg . per cent. and averaged 50 μg . on the second.—I. Leitch.

4488

AWAD, F. I. Pine (cobalt deficiency) in lambs. *Vet. Rec.*, 1955, 67, 59-60. [London Sch. Hyg. Trop. Med.]

Cobalt deficiency was produced in lambs fed on crushed oats, flaked maize and hay. The development of deficiency was prevented by a supplement of Co, and also in 4 lambs by a supplement of faeces collected from normal sheep.—D. Duncan.

4489

SOKOLOVA, L. M. Znachenie kobal'ta dlya selskokhozyastvennykh zhivotnykh. [Importance of cobalt for farm animals.] *Veterinariya*, 1954, 31, No. 5, 49-55.

In regions where animals develop anaemia, 1 g. tablets are recommended, 1 tablet per sheep every 10 days, of 0.96 g. sodium chloride and 0.04 g. cobaltous chloride, i.e., 40 mg. or 10 curative single-day doses for sheep. In the absence of tablets cobalt can be used in the form of cobaltous chloride powder. The following doses are recommended: prophylactic for sheep and goats 2 mg., lambs 1 mg., pigs and calves 5 mg., adult cattle 10 mg.; therapeutic for sheep and goats 3 mg., lambs 2 mg., pigs and calves 10 mg., adult cattle 20 mg.—H. Scherbatoff.

4490

GRASHUTS, J. Klinische lessen over sporenelementen. [Clinical lectures on trace elements.] *Tijdschr. Diergeneesk.*, 1955, 80, 199-213. [Inst. Moderne Veevoeding "De Schothorst", Hoogland.]

The first lecture deals with cobalt and vitamin B₁₂.

4491

BLAXTER, K. L. and SHARMAN, G. A. M. Hypomagnesaemic tetany in beef cattle. *Vet. Rec.*, 1955, 67, 108-115. [Hannah Dairy Res. Inst., Kirkhill, Ayr.]

Mg and Ca were estimated in samples of blood serum from calves on 20 farms near Inverness, where muscular dystrophy was known to occur. All were beef-rearing farms where the cows were kept indoors throughout the winter and the calves, born in the first 3 months of the year, received until May little or no food except the milk of their dams. Serum Mg values at birth were within the accepted normal range of 2 to 2.5 mg. per 100 ml., but tended to fall slowly in the first 2 months of life, sometimes below 0.75 mg. per 100 ml. Serum Ca was normal or high. The fall in serum Mg was greater on some farms than on

others, but no abnormality was seen on many farms except muscular dystrophy, which was not correlated with the occurrence of low serum Mg. One calf in 1953 and 2 in 1954 had tetany, with serum Mg below 0.8 mg. per 100 ml., but some calves with lower concentrations had no clinical disturbance.

The tendency for serum Mg to fall was reduced in calves given 500 mg. Mg daily, but even so some calves had values of 1.2 to 1.39 mg. per 100 ml. In some calves with serum Mg below 0.8 mg. per 100 ml. serum Ca also fell.

It is considered that the neuromuscular disorder due to low blood Mg has an incidence of about 5 per cent. on these farms and that it is purely nutritional in origin. A high Ca:Mg ratio in the bones is useful in diagnosis of the condition.

D. Duncan.

4492

VAN REEN, R. and PEARSON, P. B. Manganese deficiency in the duck. *J. Nutrition*, 1955, 55, 225-234. [McCollum-Pratt Inst., Johns Hopkins Univ., Baltimore, Md.]

Ducklings were fed from 2 to 21 days of age on a simplified ration of casein 25, gelatine 5, maize oil 4, DL-methionine 0.3, purified vitamins and minerals (excluding manganese) and glucose to 100. Twenty-two birds received the ration and distilled water to appetite, and finished with a mean weight of 700 g. Parallel groups that received the same ration with a supplement of either 20 or 40 mg. manganese, added as the sulphate, per kg., weighed 890 and 960 g., respectively.

Perosis occurred among the unsupplemented birds, and to a less extent among those receiving the lower level of Mn. It is concluded that the Mn requirement of the duckling for growth and normal development is approximately 40 mg. per kg. ration.

In further trials ducklings were given the same basal ration with and without a supplement of 78 mg. Mn per kg. The birds were then killed and their livers were analysed for selected B vitamins. The control livers had a mean content of 13 mg. nicotinic acid, 1.6 mg. riboflavin, 0.6 mg. free pantothenic acid and 4 mg. bound pantothenic acid per 100 g. moist tissue, and the values for the supplemented group were not significantly different.

Assays of enzyme activity were also made on the liver samples. The Mn supplement apparently had no effect on the contents of diphosphopyridine nucleotidase, cytochrome oxidase, catalase and isocitric dehydrogenase, but the alkaline phosphatase activity of the Mn-deficient livers was only one-half that of the livers of the supplemented birds. Examination of other tissues showed a similar effect in plasma, heart and kidney tissues,

but no difference in brain samples. Further tests indicated that the reduction in enzyme activity could not be explained by the presence of an inhibitor in the deficient tissues.—K. J. Carpenter.

4493

SINCLAIR, D. P. and ANDREWS, E. D. Goitre in new-born lambs. *N.Z. Vet. J.*, 1954, **2**, 72-79. [Dept. Agric. Res. Stat., Manutuke.]

In 1952 a severe outbreak of goitre occurred with a high mortality in lambs from young ewes. The following year a trial was made in which ryegrass-clover pasture was compared with kale, half the ewes on each type of feed being given KI for 6 weeks. The ewes were older than in the previous year. The incidence of severe goitre was higher in the lambs borne to ewes on kale without KI than in other groups. The goitre was associated with longer duration of pregnancy. In the trial, mortality was not as high as in the previous year, but this may have been influenced by the age of the ewes and by the weather. Goitre in surviving lambs did not affect subsequent growth rate to weaning.—T. D. Bell.

4494

CARE, A. D. Goitrogenic activity in linseed. *N.Z. J. Sci. Technol.* [A], 1954, **36**, 321-327. [Canterbury Agric. Coll., Lincoln.]

Goitre was caused in mice by replacing 50 per cent. of the control ration by linseed meal, but did not occur when KI was added to the drinking water.

In an experiment with 5-year-old ewes given a diet containing 20 per cent. linseed meal from tupping to lambing, goitrous lambs were produced. The lambs of ewes receiving a similar diet, but with supplements of KI or L-thyroxine, were normal.

The action of cyanogenetic glucosides, in this case thought to be linamarin, in producing goitre is discussed.—T. D. Bell.

DISEASES OF METABOLISM

4495

THEME, E. Die Bedeutung des Stoffwechsels beim sog. Herztod der Schweine. [Metabolism in so-called heart failure in pigs.] *Arch. Tierernährung*, 1954, No. 5, Beihefte, 35-49. [Vet. Pathol. Inst., Karl Marx Univ., Leipzig.]

On the basis of a review of the literature, with special reference to post-mortem findings and differential diagnosis from anaemia and degenerative changes caused by vitamin deficiency, this sudden death, with enlarged heart, is attributed to a disturbance of carbohydrate and mineral,

especially K, metabolism, associated with excess production of insulin and defective adrenal function.—I. Leitch.

4496

ROGERS, J. A. A contribution to a better understanding of ketosis in dairy cows. *J. Amer. Vet. Med. Assoc.*, 1955, **126**, 129-130. [New Bolton Centre, Univ. Pennsylvania, Kennett Square.]

The "denko test" for ketone bodies is described. This test was found to be the best for the diagnosis and for following the progress of ketosis. From a study of 298 cases it was concluded that ketosis should be regarded as developing gradually and lasting for several weeks, not as a disease which comes quickly and is only of a few days' duration.

T. D. Bell.

4497

PUGH, P. S. Hyperketonaemia and foetal death in the sheep. *Vet. Rec.*, 1954, **66**, 645-652. [Sch. Vet. Med., Univ. Cambridge.]

Ketone body and sugar values were estimated in the blood of normal ewes and ewes with idiopathic pregnancy toxæmia, induced starvation ketosis, placental lesions or enzootic abortion. High ketone and low sugar values were found in the first 2 disorders. The presence of live lambs seemed to be connected with this blood condition. The results are discussed in relation to the survival of the foetus.—T. D. Bell.

4498

SAMPSON, J., TAYLOR, R. B. and SMITH, J. C. Hypoglycemic coma and convulsions in fasting baby lambs. *Cornell Vet.*, 1955, **45**, 10-15. [Coll. Vet. Med., Urbana, Ill.]

Blood sugar values in fasted and non-fasted lambs aged between a few hours and 4 days at the start of the observations were estimated. In the first trial there were 6 fasted and 3 control lambs. The second trial had 7 pairs of twins, one of each pair acting as control. Daily blood sugar values, body temperatures and bodyweights are recorded from the time when fasting was started till the fasted lambs were in a coma, convulsions or a stupor. The time taken for these signs to develop was usually about a week, 4 days being the shortest and 16 days the longest. Blood sugar values, body temperatures and bodyweights all decreased during starvation. Injection of glucose relieved the signs. The onset and recovery were similar to those in baby pigs, but took much longer.—T. D. Bell.

4499

BEGOVIĆ, S., SABLIJAN, I. and STERN, P. Die Curare-artige Wirkung des Acetylcholins in der Entstehung der Paralyse puerperalis bei

N.A. and R., July 1955

Kühen. [The curare-like effect of acetylcholine in relation to puerperal paresis in cows.] *Naturwissenschaften*, 1955, 42, 21. [Pathophysiol. Inst., Vet. Fac., Univ. Sarajevo.]

The hypothesis is advanced that milk fever is caused by absorption of an excess of acetylcholine from the milk and possibly from the uterus. It is stated that milk is rich in acetylcholine and that neither the milk nor the serum of cows contains cholinesterase. Cows and calves treated with atropine responded to injection of acetylcholine with a syndrome resembling milk fever, which disappeared after injection of KCl.—D. Duncan.

POISONS OCCURRING IN FOOD

4502

HARVEY, J. M. and MOULE, G. R. Fluorosis of Merino sheep in Queensland. 1. How the disease is caused. 2. Studies of transmission, water treatment and amelioration. *Queensland Agric. J.*, 1954, 79, 291-298; 357-359. [Animal Health Stat., Yeerongpilly.]

1. The signs of fluorosis in sheep are described briefly. They were first observed in Queensland in 1940, and investigations were started in 1945. Maps showing the location and distribution of water supplies containing less than 1, 1 to 2, 2 to 5, 5 to 10 and more than 10 p.p.m. fluoride are presented. Mild fluorosis could be detected in sheep getting 2 p.p.m. fluoride in their drinking water from birth, and as the amount of fluoride increased the disease became more severe, but dangerous proportions were reached only when water containing 10 p.p.m. fluoride was habitually taken.

2. When ewes with day-old lambs were given drinking water with 10, 5 or 2 p.p.m. fluoride there was no difference in the fluoride content of their milk, which remained less than 0.2 p.p.m.

During the next 12 months the same 3 groups

of ewes continued to receive the same drinking water as before, and after lambing they were given a ration poor in lime. Still there was no change in the fluoride content of the milk. The second crop of lambs were killed at 6 weeks of age. The bones and teeth of those from ewes getting 10 or 5 p.p.m. fluoride had much higher levels of fluoride than those of lambs from ewes getting 2 p.p.m. or no fluoride in their drinking water. The high fluoride level in bones and teeth did not seem to affect the young lambs. Abnormal lambs have been reported from ewes getting 15 to 20 p.p.m. fluoride in drinking water.

On a field scale it is difficult to eliminate fluoride from drinking water.

The provision of lime, protein and phosphate supplements for 3-month-old lambs getting a diet poor in these, and drinking water containing 5 or 10 p.p.m. fluoride, did not prevent signs of fluorosis developing. The fluorosis did not appear to affect wool production. Inability to graze or to chew hard feed may reduce meat production, but there is no build-up of fluoride in the edible carcass, so there is no danger to consumers.—T. D. Bell.

4503

TESINK, J. Fluorvergiftiging bij runderen en haar beïnvloeding door het toedienen van aluminiumsulfaat. [Fluorine poisoning in cattle and the effect of giving aluminium sulphate.] *Tijdschr. Diergeneesk.*, 1955, 80, 230-246. [Kockengen.] English, French and German summaries.

Industrial fluorine poisoning is discussed and experiments with cattle given fluorine alone or with aluminium sulphate are described, which confirm that aluminium sulphate prevents in part the absorption of fluorine and can render toxic concentrations non-toxic. The aluminium sulphate may be put in feeding cake.—I. Leitch.

4504

WAHLSTROM, R. C., KAMSTRA, L. D. and OLSON, O. E. The effect of arsenic acid and 3-nitro-4-hydroxyphenylarsonic acid on selenium poisoning in the pig. *J. Animal Sci.*, 1955, 14, 105-110. [Dept. Animal Husb., S. Dakota State Coll.]

The results of 2 experiments showed that complete protection against poisoning by diets containing up to 10 p.p.m. selenium could be given to pigs by including 0.02 per cent. arsenic acid or 0.005 per cent. 3-nitro-4-hydroxyphenylarsonic acid in the ration. Half these quantities gave partial protection. The effectiveness was judged by the comparative rates of gain and mortality. On rations free from Se the arsenic compounds slightly improved growth rates. There was some evidence that individuals and breeds varied in

their susceptibility to Se poisoning, Durocs being more susceptible than Hampshires or Spotted Poland Chinas in these experiments. In the second experiment the higher levels of both drugs increased blood clotting time slightly.—T. D. Bell.

4505

HANSEL, W., OLAFSON, P. and MCENTEE, K. The isolation and identification of the causative agent of bovine hyperkeratosis (X-disease) from a processed wheat concentrate. *Cornell Vet.*, 1955, 45, 94-101. [Cornell Univ., Ithaca, N.Y.]

Hyperkeratosis was caused in bull calves of about 250 lb. liveweight by giving them fractions of breadcrumbs from the slicing and packing department of a bakery. The fresh bread did not cause hyperkeratosis. The method of isolating the fractions is described. The cause of the disorder was found to be a highly chlorinated naphthalene, but the source of the impurity in the breadcrumbs is not known.—T. D. Bell.

4506

McCLYMONT, G. L. Paresis associated with spinal cord myelin sheath degeneration in new born pigs. *Austral. Vet. J.*, 1954, 30, 345-346. [Nutrit. Res. Lab., Vet. Res. Stat., Glenfield, N.S.W.]

The post-mortem examination of 2 baby pigs of a litter which died with clinical signs of paresis of the limbs revealed degeneration of the myelin sheath of the medulla and the thoracic spine. In the previous season the litters from all 6 sows of the herd had died with similar clinical signs. At that time the sows had recently been moved on to a white-clover pasture. When the later cases of paresis occurred 1 lb. meatmeal had been included in the ration. The cause of the myelin degeneration is obscure, but it is suggested that it may have been due to some toxic substance in the white clover, possibly a cyanogenetic glucoside.

T. D. Bell.

4507

BAGLEY, R. A. Toxic reaction to dihydrostreptomycin in young poults. *Poultry Sci.*, 1954, 33, 1276-1278. [Dept. Vet. Sci., Utah State Agric. Coll., Logan.]

Poults, 11-day-old, that received intramuscular injections containing 50 to 250 mg. dihydrostreptomycin showed an immediate toxic reaction, with leg weakness and the onset of a comatose condition; some birds died, but most recovered in 6 hr. The reactions occurred whether or not the birds had been receiving antibiotics in their diet. Chicks were less sensitive than poults, but 500 mg. dihydrostreptomycin were sufficient to produce inco-ordination in a chicken weighing 1.75 lb.

K. J. Carpenter.

4508

FOX, H. J. and FRANCE, W. H. Bracken poisoning in cattle. *Vet. Rec.*, 1954, 66, 711-712.

In 4 herds on hill-grazing bracken poisoning was treated with vitamin K or nicotinamide. Blood counts in affected animals showed low leucocyte counts and few thrombocytes or none. It is suggested that where there is a risk of bracken poisoning, or in herds where it has occurred, frequent blood counts should be made so that early treatment can be given before the obvious signs appear, when it may be too late to save the animals. The use of nicotinamide or vitamin K is recommended.—T. D. Bell.

4509

BULLINGTON, T. H., BYRD, C. E. and HARRIS, T. W. Urea poisoning in the bovine. *Nor. Amer. Vet.*, 1955, 36, 107-109. [Fayetteville, Tenn.]

Three cases of urea poisoning in dairy cows due to badly mixed feeds are reported.—T. D. Bell.

IMMUNITY

4510

ČERNÝ, L., DRAŽAN, J., MENŠÍK, J. and KLÍMA, D. Kolostrální imunita při brucellose skotu. [Colostrum immunity in brucellosis of cattle.] *Šborn. čsl. Akad. Zéměd.*, 1954, 27, 617-638. [Kat. Vet. Fak., Vysoké Škol. Zéměd., Brno.] Russian and English summaries.

Calves of cows infected with brucellosis have no antibodies but these appear in the blood after the calf has suckled for 2 hr., the concentration being similar to that in the colostrum. Antibodies were still found in the blood serum of the calf after 113 to 129 days. The antibody content could not be estimated from the amount of γ -globulin in the blood serum. The amount of γ -globulin in the blood serum of the calf which received colostrum at birth increased by 3 to 5 times in 24 hr. (From summary.)

J. S. Thomson.

4511

VEGORS, H. H., SELL, O. E., BAIRD, D. M. and STEWART, T. B. Internal parasitism of beef yearlings as affected by type of pasture, supplemental corn feeding, and age of calf. *J. Animal Sci.*, 1955, 14, 256-267. [Georgia Agric. Exp. Stat., Experiment.]

In 1950 and 1951 the effects of 3 types of pasture for winter grazing: a temporary pasture of oats, ryegrass and crimson clover; fescue and white clover; and crimson clover, on internal parasites of yearling beef calves were studied, some animals on each pasture also getting a supplement of maize. In 1952 and 1953 the same pastures were used, no supplements were given, but animals 11 and 8

N.A. and R., July 1955

months old were compared. Calves on the fescue pasture, which was inadequate, had higher worm loads than those on the other pastures, and though there were large counts of parasitic larvae on the pastures, the better feeding provided by the temporary and crimson clover pastures checked the development and harmful effects of the parasites. When given maize supplements calves had fewer worms than comparable animals not getting supplements. Younger calves had more worms than older in similar conditions.—T. D. Bell.

GERRIETS, E., WEENER, C. and STAHL, H. Experimentelle Untersuchungen über die gesundheitsfördernden Eigenschaften der Altstreuverfahren bei der Kükenaufzucht. 2. [Experimental studies of the beneficial effects of

deep litter in rearing chicks. 2.] *Arch. Geflügelk.*, 1954, 18, 459-468. [Abt. Geflügelk., Humboldt Univ., Berlin.] English summary.

A previous experiment (Abst. 4007, Vol. 24) was repeated with 2 groups of 50 chicks, one a control and the other infected with *Salmonella pullorum*, on sawdust litter changed frequently, and infected groups on built-up old horse manure and on built-up old poultry litter (a mixture of garden compost and poultry manure). Mortality from *S. pullorum* in the infected groups in the above order was 82, 77 and 89 per cent.; that is, built-up litter offered no advantage. The slightly better results with horse manure are ascribed to its warmth.

After a lapse of 35 days none of the litters transmitted the infection to fresh chicks.

W. M. Deans.

7. BOOK REVIEWS

4513

RUSSELL, E. J. *World population and world food supplies*. George Allen and Unwin, Ltd., London, 1954, pp. 513. Price 50s.

The well-chosen title of this book may be taken as an abridgement of the headings of its first and last chapters, the one which states the problem and the other which summarises the trends of supplies. Between these chapters Sir John Russell has brought together a mass of data drawn from official publications of FAO, the Commonwealth Economic Committee and Ministries of Governments and the result is an up-to-date compilation such as has not been equalled in other writings on the subject. In succession there come under review the production and, so far as the available information allows, the consumption of food in the United Kingdom, the Northern European intensive and the Mediterranean peasant areas, Africa with both native peasant and European farming, India and Pakistan with their population problems, the rice-exporting countries of the Far East and the food-exporting countries both actual in the North American and Australasian, and potential in the South American continents. The tables in the book are numerous and they are supplemented with 45 diagrams, many of which have been specially drawn, and with the same number of illustrations.

Such a compilation might easily have been dull and uninteresting but the former Director of Rothamsted Experiment Station has, from his own world-wide travels, introduced reminiscences and is able to emphasise to his reader what were his own personal impressions. On occasions which, unfortunately, are all too frequent, he has had to record the unwillingness and the failure of the

inhabitants of underdeveloped areas to co-operate in the work of improving their methods of agriculture. At the same time there does not pass unnoticed the impossibility of rushing development however well-intentioned may be the schemes for so doing.

From this objective analysis there are advanced neither gloomy prognostications nor cheerful prophecies. Rather is the reader left to draw his own conclusions, though the author does admit to possessing a tempered optimism. A conclusion of the greatest consequence is concerned not with the production or consumption of food but with the background of the training of the farmer. For the change from peasant agriculture as it exists over so much of the world to the complex systems attained, for example, in Scandinavia, Britain and New Zealand there will be required both a high standard of scientific attainment and a desire for the application of scientific methods to agriculture. This book tells clearly how many of the difficult problems have already been overcome and indicates many of those that await solution before the world's hungry population can be adequately fed.—D. Harvey.

4514

BLOCK, R. J., DURRUM, E. L. and ZWEIG, G. (with LESTRANGE, R., WINGERD, W. H. and WEISS, K. W.) *A manual of paper chromatography and paper electrophoresis*. Academic Press, Inc., New York, 1955, pp. 484. Price 64s.

This is a practical manual of paper chromatography and electrophoresis, although theoretical aspects of both techniques are considered in introductory chapters. About four-fifths of the book

is concerned with paper chromatography, all the major constituents of biological material being discussed. Amino-acids and their derivatives, aliphatic acids, steroids, bile acids, purines and pyrimidines and their derivatives, carbohydrates, phenols, aromatic acids, porphyrins, vitamins, antibiotics and plant growth substances are dealt with in some detail. Further chapters are devoted to the chromatography of a wide range of miscellaneous organic compounds and of inorganic substances. It is clearly impossible for any work of this size to be complete, but this account is certainly adequate in the range of compounds considered and in the detail in which basic manipulations are described to provide a starting-point for any worker wishing to extend his practical experience. A particularly satisfactory feature of the book is the large number of tests described for the detection of compounds on paper.

Although the section devoted to paper electrophoresis is much shorter than that on paper chromatography, it provides a timely account of this technique, which is being increasingly used in biochemistry. The emphasis is inevitably on the separation of proteins and amino-acids, but the experimental details given should provide an adequate basis for the application of the procedures to the separation of other types of material.

The book is excellently printed and contains a detailed index and an extensive bibliography. It should prove a useful addition to the library of any chemist or biochemist.—H. G. Bray.

4515

LOVERN, J. A. *The chemistry of lipids of biochemical significance.* Methuen & Co., Ltd., London, 1955, pp. xiii + 132. Price 8s. 6d.

This book, which is one of Methuen's series of "Monographs on Biochemical Subjects", is based on a series of lectures given by the author for the Department of Biological Chemistry of the University of Aberdeen in 1952. Four of the 5 chapters are modified versions of these lectures and include discussion of additional information published in 1953. These chapters give a comprehensive, yet succinct account of the chemical structure of the different classes of lipids, the nature of their physicochemical state in tissues, their dynamic condition, particularly as revealed by modern isotope studies, and a discussion of the biochemical functions of lipids. As can be appreciated even from this very brief summary of the main themes, the title of the book may be misleading in its suggestion of an over-riding emphasis on pure chemistry, which is far from the truth. The additional chapter gives an account of the preparation and analysis of lipids, a critical review which, in the light of the author's wide experience, is of especial value to the research worker in this

field, where there has hitherto been little guidance.

Although there are available many compendious modern books on the chemistry and biochemistry of lipids, most suffer from being mere catalogues of facts. This monograph, on the other hand, succeeds in giving the reader a clear, integrated, general picture of lipid biochemistry and, as such, can be commended both to the research worker and to the student.

Full references are given at the end of each chapter and a broad subject index at the end of the book.—G. A. Garton.

HARRIS, R. S., MARRIAN, G. F. and THIMMANN, K. V. (Eds.) *Vitamins and hormones. Advances in research and applications.* Volume 12. Academic Press, Inc., New York, 1954, pp. xi + 305.

4519

BAILEY, A. E. (Ed.) *Cottonseed and cottonseed products. Their chemistry and chemical technology.* Interscience Publishers, Inc., New York, 1948, pp. xxiii + 936. Price 125s.

This is a survey by specialist authors of cottonseed and of the cottonseed industry, with chapters on the history, production and consumption of cottonseed, the biology of cottonseed, and the manufacture of cotton, cottonseed oil and cottonseed meal. The nutritional value of cottonseed meal for livestock is discussed by F. Hale and C. M. Lyman. In the United States cottonseed meal is most widely used in the rations of cattle and sheep and to a growing extent in the rations of chickens and turkeys. It is at present unsuitable for laying hens owing to discolouration of the eggs on storage. Cottonseed meal is also mixed with other protein supplements such as tankage and given to pigs.—D. H. Shrimpton.

4520

AXELSSON, J. *Foderkonserveringsnytt. [Fodder conservation.]* Bokförlaget Minerva, Upsala, 1954, pp. 92.

This small book is well printed and clearly and

N.A. and R., July 1955

concisely written. It deals with techniques of harvesting green crops, ensiling, which occupies more than half the book, haymaking and artificial drying. The treatment is conventional. An interesting graph shows sales of A.I.V. fluid in Sweden to have reached a maximum of over 7000 tons in 1946, and to have fallen to about one-tenth of the maximum by 1953. It has been

replaced by other acids, *e.g.*, formic acid, and more commonly by molasses, potatoes and other proprietary preservatives, of which some appear to have little or no effect on the conservation process. There is a short chapter on the use of silage, and the final chapter compares the effects of artificial and field drying on the composition of the product. I. Leitch.

8. FOOD AND AGRICULTURE ORGANIZATION (AND OTHER ORGANIZATIONS) OF THE UNITED NATIONS

Monthly Bulletin of Agricultural Economics and Statistics.

Vol. 4, No. 3, March 1953, pp. 52. Price \$0.50.

Vol. 4, No. 4, April 1953, pp. 48. Price \$0.50.

Vol. 4, No. 5, May 1953, pp. 52. Price \$0.50. Economic aspects of cocoa consumption.

Yearbook of Fishery Statistics, 1952-53, Vol. 4, Part 1.

Production and catch. Rome, Italy, 1955. Price \$3.00.

Problems of food and agricultural expansion in the Near East.

Rome, Italy, 1955, pp. 53. Price \$0.50.

This publication is in 2 parts, the first the Report of the FAO Regional Consultation on the Selective Expansion of Production and Consumption in the Near East, the second a document prepared for and submitted to that Consultation. It was held at Beirut in September 1954 and attended by delegates from Egypt, France, Iran, Iraq, Lebanon, Syria and Yemen, and by observers from interested international organisations. With the rapid expansion of cereal production, the decline in cotton production and the failure of the livestock industry to increase output as the main trends in the period just before the meeting, changes in food consumption were towards the substitution of wheat for maize and increases in the uses of sugar and tea. The real need was for the greater production of foods rich in protein. Agricultural programmes towards this end are considered and the necessity is emphasised for the co-ordination of nutrition activities with these.

Methods of collecting current agricultural statistics.

Rome, Italy, March 1955. Price \$3.00.

The manual prepared under the direction of Dr. R. D. Narain describes the methods used in a large number of countries for the collection of current statistics on area, production of crops, livestock numbers and livestock products. The pattern is standardised under 8 headings: administrative division; agricultural statistics collected; collection of data, unit, type and method of enumeration; sampling methods; organisation for collection and tabulation; time schedule; processing of data; publications. The whole is included in a loose-leaf binder to permit incorporation of fresh material as it becomes available.

Report on the 1950 World Census of Agriculture Vol. 1.

Rome, Italy. First instalment, March 1955. Price \$2.00.

The first instalment of the Report gives the results obtained for 30 of the participating countries. The data are presented under 11 headings: holding and tenure, land utilisation, agricultural population, employment in agriculture, crops, livestock and poultry, agricultural technology, fertilisers and soil dressings, irrigation and drainage, fragmentation, wood and fishery products. For 10 of the countries it has been possible, in addition to giving the information regarding the total number of holdings, to provide a further classification according to their size. As the analyses for the remaining countries become available they can be incorporated in the loose-leaf binder which is provided.

METABOLIC AND REGULATORY DISTURBANCES OF FOOD INTAKE	871	CONCLUSIONS AND PRACTICAL SUGGESTIONS	879
INTERACTION BETWEEN CONSTITUTIONAL AND EN- VIRONMENTAL FACTORS, AS EXEMPLIFIED BY THE ROLE OF PHYSICAL ACTIVITY	875	REFERENCES	882

METABOLIC AND REGULATORY DISTURBANCES OF FOOD INTAKE

METABOLIC AND REGULATORY FACTORS

In an earlier report (Mayer, 1953a) an attempt was made to classify forms of obesity on the basis of a characteristic etiological element: genetic, traumatic and environmental factors were thus distinguished. Such a classification is of pragmatic interest in that it identifies modes of production of obesity, particularly experimental obesity; thus, the hereditary obese-hyperglycaemic and yellow forms of obesity in mice are produced by breeding, the goldthiogluucose and hypothalamic obesities by traumatic intervention. This taxonomic approach, however, sheds very little light on the mechanism of the disturbance. In fact, the mechanisms underlying two forms of hereditary obesity may be entirely different, and a traumatic intervention may reproduce one of the hereditary disturbances. Consider, for example, two forms of "constitutional" obesity in mice: the hereditary obese-hyperglycaemic syndrome appears to be a genetically transmitted endocrine disturbance; "spontaneous" hypothalamic obesity in mice is due to an inherent tendency of the ventromedial nuclei to degenerate. One form of traumatic obesity, resulting from a hypothalamic lesion produced by surgery, will reproduce the

second form of constitutional obesity, yet, as will be readily apparent later on, have very little in common with the other genetic kind. Doubtless similar examples could be worked out for excessive thinness.

Furthermore, the distinction between genetic and traumatic factors on the one hand, and environmental factors on the other hand, is artificial in view of the interaction of constitutional and environmental factors. For example, even granted that the characteristic element in the etiology of a form of obesity is, say, hypothalamic, the obesity would still not develop if food were not available, or were too diluted, or too high in protein, if water were not freely available, or if the animals were exercised excessively. A multiplicity of factors always seems to be involved.

If one thus attempts to classify forms of obesity (or leanness)¹ according to the mechanism involved, it would appear that such a classification

¹ In this section, obesity and hyperphagia, excessive leanness and anorexia, are systematically associated. This equivalence does not correspond strictly to all observed facts. Reference has already been made to the fact that genetically obese mice, underfed to the point of being underweight, are still obese as regards body composition (Alonso and Maren, 1954). Mention has been made also of the interesting result of Fenton and colleagues (Fenton and Carr, 1951; Fenton and Dowling, 1953) that, in at least one strain of mice, changing the animals to a high-fat diet causes an increase in oxygen intake which limits the

should be based on consideration of the mechanism of regulation of food intake. It has been shown in Part I of this Review (p. 607) that two types of factor, metabolic and regulatory, intervene to modify the mode of action of this mechanism. One is thus led to divide abnormalities of food intake (and body fat) into two broad classes:

(a) Forms in which the central (nervous) mechanism for regulating food intake functions normally but in which there is a disturbance in tissue metabolism which abnormally promotes (or limits) the accumulation of fat ("metabolic" obesity or leanness);

(b) Forms in which metabolism is normal but in which central (nervous) disturbances (of physiological or psychogenic origin) modify the regulation of food intake so as to cause obesity or leanness.

Environmental conditions, apart from their permissive role, may intervene in two ways, corresponding to the regulatory and metabolic distinction between constitutional factors. They may cause metabolic disturbances, or place the organism in a situation where its usual metabolic response to a stimulus is eliminated, as may occur in obesity due to immobilisation (Ingle, 1949) or in nutritional obesity (Fenton and Carr, 1951; Fenton and Dowling, 1953). It thus seems legitimate to accept the general validity of the distinction between metabolic and regulatory disturbances, keeping in mind the possibility that there may be forms which would in part fall under both headings. For example, excessive cortisone-like secretion or administration may prove to be the cause of both regulatory and metabolic hyperphagia (Heinbecker and Pfeifferberger, 1950; Wolfson, 1954).

EXPERIMENTAL DIFFERENTIATION BETWEEN METABOLIC AND REGULATORY OBESITY

An illustration of the physiological significance of the new mode of classification is provided by recent experimental studies. Until recently, the different forms of obesity listed in Table 1, Part 1 (p. 608) had been established and examined in separate animal species or at least in separate strains or stocks, and the interpretation of observed metabolic differences was difficult, if not impossible, since deviations from the normal would vary according to the metabolic "substrate" on which hyperphagia and obesity were superimposed, and it was impossible to differentiate between non-specific sequelae of hyperphagia and obesity and

weight gain. Still, all in all, the association of hyperphagia and development of obesity (obesity in the "active" phase) is sufficiently universal to permit the use of the terms as almost equivalent. This seems even more legitimate for the opposite disorders.

idiosyncrasies of the syndrome of possible etiological significance.

In the course of the past two years, it has been found possible to induce goldthiogluconic obesity in thin littermates of genetically obese mice (Marshall and Mayer, 1954; Mayer and Zighera, 1954); obesity was also induced, again in mice and, in particular, in thin littermates of genetically obese mice, by hypothalamic lesions (Mayer, French *et al.*, 1955). Obesity induced by these two methods can reach a degree similar to that reached in the Mendelian recessive form. The order of magnitude of the rates of weight gain is similar.

All three types of obesity are characterised by a positive energy balance when the animals are allowed free access to food. However, the manner in which the positive energy balance is arrived at differs considerably in the different types. In the hereditary obese-hyperglycaemic syndrome, it is the result of a moderate (25 per cent. above normal) degree of hyperphagia (Mayer, Dickie *et al.*, 1951), an oxygen consumption which when related to body surface is very low (as much as 40 or 50 per cent. below normal) (Mayer, Russell *et al.*, 1952) and much reduced physical activity (Mayer, 1953b). Thyroid hypofunction can be excluded as a cause of the low oxygen consumption and activity (Goldberg and Mayer, 1952). In goldthiogluconic obesity, the positive energy balance is directly related to the considerable degree of hyperphagia (50 to 75 per cent.), associated with a basal oxygen consumption which follows the surface law, and normal spontaneous activity (Marshall and Mayer, 1954). In mice made obese by hypothalamic lesions, the surplus energy is due to marked hyperphagia (50 to 100 per cent.), normal basal oxygen consumption, and reduced activity (Mayer, French *et al.*, 1955).

The different types of obesity differ as regards reaction to caloric dilution of the diet and to composition of the diet. Goldthiogluconic obese mice show a poor adjustment to dietary dilution (Owen *et al.*, 1953). Their behaviour is similar to that of rats made obese by hypothalamic lesions (Kennedy, 1950). By contrast, mice with the hereditary obese-hyperglycaemic syndrome give a much more normal response to dietary dilution (Parson *et al.*, 1954). As regards diet composition, hypothalamic and goldthiogluconic obese mice show the greatest caloric intake and weight gain on a high-fat diet and a consumption greater than normal on a high-carbohydrate diet, while on a high-protein diet they gain least or even, in the case of goldthiogluconic obesity, lose weight (Marshall and Mayer, 1954; Mayer, French *et al.*, 1955). By contrast, mice with the obese-hyperglycaemic syndrome gain most weight on a high-carbohydrate diet, gain weight slowly on a high-protein diet and

gain least on a high-fat diet (Mayer and Jones, 1953).

Low environmental temperature again gives rise to two different types of reaction. Goldthioglucose obese (Davis and Mayer, 1954a) and hypothalamic obese (Barnett and Mayer, 1954) animals resist cold as well as normal animals, but mice with the obese-hyperglycaemic syndrome are unable to withstand exposure to cold (5°C.) and may die within from 1 to 3 hours. The obese-hyperglycaemic animals, incidentally, have been shown to exhibit normal "physical" reactions to cold (vasoconstriction, pilo-erection, shivering, poly-pnoea) but their "chemical" thermogenesis is impaired (Davis and Mayer, 1954a, b; 1955a). Exposure to electromagnetic waves, which has been shown to be a substitute for chemical thermogenesis (Davis and Mayer, 1955b), protects the genetically obese mice against exposure to cold (Davis and Mayer, 1954b).

The obese-hyperglycaemic animals generally show high blood glucose and glycosuria (Mayer, Bates *et al.*, 1951). In a small proportion of the animals the blood glucose level is within the normal range, but even in them it can be immediately raised to "diabetic" levels by a single injection of growth hormone, to which the mice with the obese-hyperglycaemic syndrome are extremely sensitive (Mayer *et al.*, 1953; Mayer and Silides, 1953). By contrast, goldthioglucose and hypothalamic obese mice show a normal blood glucose level which is as resistant to the diabetogenic effect of growth hormone as that of normal rodents¹ (Mayer and Zighera, 1954; Mayer, French *et al.*, 1955). A similar contrast is exhibited with cholesterol, the blood level of which is very high in the genetic syndrome but only slightly raised in the two other forms¹ (Mayer and Jones, 1953; Brobeck, 1946; Drachman and Tepperman, 1954). The hypercholesterolaemia of genetically obese mice also shows undue sensitivity to growth hormone. The same mice show a peculiar type of insulin resistance, characterised by absence of convulsions and by spontaneous return to normal levels of blood glucose even in the fasted state (Shull and Mayer, *in press*). By contrast, goldthioglucose and hypothalamic obese mice when injected with insulin in the absence of food are thrown into convulsions as easily as non-obese animals (Mayer

and Zighera, 1954; Mayer, French *et al.*, 1955). The mice with the hereditary obese-hyperglycaemic syndrome show hyperplasia of the islets of Langerhans and increased pancreatic insulin secretion (Mayer *et al.*, 1953; Wrenshall *et al.*, 1955). Total carcass protein is decreased in the genetic form, but is normal in the other two types of obesity (Bates, Nauss *et al.*, 1955).

Observed differences in fat metabolism also emphasise the marked differences between the chemical mechanisms of the three syndromes (Guggenheim and Mayer, 1952; Bates, Mayer and Nauss, 1955a, b; Bates, Zomzely and Mayer, 1955; Mayer, Hagman *et al.*, 1955). In the hereditary obese-hyperglycaemic syndrome, a profound shift toward lipogenesis is observed, both *in vivo* and *in vitro*, alike in the carcass and the liver, even under conditions which normally would preclude fat synthesis, such as underfeeding, chronic or suddenly imposed, and even, in the experiments on "instantaneous" (half-hour) incorporation of ¹⁴C-labelled acetate into liver and carcass fatty acids, a 24-hour fast. Goldthioglucose obesity presents an entirely different picture. With it mice show increased lipogenesis compared with their non-obese littermates only in the measure that they are allowed to overeat. Incidentally, the fact that a difference in ¹⁴C incorporation was established between animals of similar fat content eliminates the possibility that it was a secondary result of hyperphagia or of extreme adiposity. Cholesterol synthesis also is increased (Mayer, 1954a). Hypothalamic obese animals show "instantaneous" incorporation of ¹⁴C-labelled acetate like that in goldthioglucose obese mice (Bates, Zomzely and Mayer, 1955; Mayer, Hagman *et al.*, 1955), although long-term studies are complicated by the curious feeding pattern of these animals (Bates, Mayer and Nauss, 1955a). Underfeeding, while it cuts down the weight of hereditarily obese mice, still leaves them with an abnormally high fat content (Alonso and Maren, 1954; see footnote, p. 871). It brings the composition of goldthioglucose obese mice back to normal. Pair-fed hypothalamic obese and normal animals still differ in composition, the hypothalamic ones containing somewhat more fat. Van Putten (1952) has shown that at least the major part of the difference could be ascribed to different spontaneous feeding patterns and could be eliminated if the animals were fed so that they consumed their food under similar conditions of spacing and timing.

Skinner box¹ studies of the different types of obese mice show that the feeding patterns of hereditarily obese mice deviate from those of normal

¹ The contrast between the hypercholesterolaemia and hyperglycaemia of the genetically obese mice and the normal picture encountered in goldthioglucose and hypothalamic obesities does not exclude the fact that old animals with either syndrome are more prone to spontaneous rise of blood glucose and cholesterol levels than mice of normal weight. It shows, however, that at least as far as mice are concerned, the association of obesity with hyperglycaemia and hypercholesterolaemia is of two entirely different types.

¹ An apparatus for studying animal behaviour, in which the rat or other experimental animal presses a bar and is rewarded by a pellet of food (Skinner, 1953).

animals; goldthioglucoase and hypothalamic obese animals show different abnormalities (Anliker and Mayer, submitted for publication).

Finally, the pathological conditions accompanying the different forms of obesity are different (Mayer, 1954*b*; 1955*a*).

EXTENSION OF THE DISTINCTION BETWEEN REGULATORY AND METABOLIC OBESITY

This evidence indicates that in the hereditary obese-hyperglycaemic syndrome the essential lesion is a metabolic disturbance, consisting in primary hyperglycaemia followed by hypersecretion of insulin which in turn causes the obesity and hypercholesterolaemia. The syndrome has been in part reproduced in thin animals by appropriate hormonal treatment (Mayer and Slides, to be published). The nature of the primary hyperglycaemia has been discussed in a preliminary fashion elsewhere (Mayer, 1955*a*) and is under intensive investigation. The central mechanism regulating food intake is probably intact but functions on signals distorted by the metabolic lesion. The hereditary obese-hyperglycaemic syndrome can thus be considered typical of metabolic obesity. By contrast, in goldthioglucoase obesity, there is no detectable primary metabolic lesion, all observed metabolic abnormalities being clearly referable to the disturbed mechanism for regulating food intake. The mechanism, although it appears to be pegged at a higher level, is still susceptible to some influences: while the higher calorie intake on high-fat compared with high-carbohydrate diets could be explained in part by differences in calorie concentration, the fact that high-protein diets lead to lower intakes than high-carbohydrate diets clearly shows that the organism is still sensitive to the peculiar "satiety" effect of high-protein diets or, alternatively, cannot tolerate large amounts of protein as it can of other dietary constituents. The goldthioglucoase obesity syndrome can thus be considered typical of regulatory obesity. The status of hypothalamic obesity is more doubtful; it is probably another example of regulatory obesity. The negative correlation of non-fasting blood sugar levels with hyperphagia (Mayer, Bates and Van Itallie, 1952) and the extreme inertness of depot fats (Bates, Mayer and Nauss, 1955*b*) in hypothalamic obese rats are probably metabolic consequences of hyperphagia rather than phenomena of primary etiological significance. It is not absolutely excluded, however, that the mechanism of the hyperphagia may be in part mediated through metabolic disturbances.

Endocrine forms of obesity are obviously metabolic; the possibility that the hyperadrenocortical types may also have some regulatory aspects has

been mentioned. The hyperphagia due to social or familial pressure is purely regulatory. So, it would appear, are most types of psychogenic obesity, though it is not impossible that primarily psychological disturbances may have some metabolic results which in turn will cause hyperphagia.

METABOLIC AND REGULATORY FACTORS IN ANOREXIA

A similar type of analysis could be attempted for anorexia, though the experimental evidence is less complete. Both metabolic and regulatory forms exist. Anorexia can be produced in the laboratory by symmetrical lateral hypothalamic lesions (Anand and Brobeck, 1951) or by injecting glucose into hypophysectomised alloxan-treated animals (Mayer and Bates, 1952). Clinically, common examples of metabolic anorexia are those accompanying disease and old age. Ohlson *et al.* (1948) have shown that older women consistently eat from 300 to 500 Cal. less daily than representative samples of young women; they further showed that women who did not enjoy full health consistently ate less than the healthy. Vinther-Paulsen (1952) and Spies and Collins (1946) have emphasised the mutually accelerating relationship of anorexia and senile debility. Panhypopituitarism, and particularly Simmonds' disease, leads to anorexia, largely at least for metabolic reasons.

By contrast, in essential human thinness, the most general picture appears to be a disproportion between physiological requirements and appetite, without any known "metabolic" basis. *Anorexia nervosa*, which, although it presents certain characteristics that are probably secondary to calorie undernutrition and that make it resemble panhypopituitarism (emaciation, senile appearance, loss of hair, achlorhydria, hypotension, hypometabolism, hypoglycaemia, amenorrhoea), can be differentiated, at least when its onset is relatively rapid, by measurement of the ketosteroid excretion and insulin sensitivity, and by the presence of pubic and axillary hair. Since its initial description by Gull (1888), explanations have shifted from purely mechanical aspects, such as possible downward displacement of the stomach (gastropexia), to purely psychological explanations.

It is pertinent to call attention to the fact that for *anorexia nervosa* it is premature to conclude that non-cortical and metabolic factors can be ruled out in the etiology of all cases. A recent typical series described by Hertz (1952) emphasises certain puzzling aspects. The sex discrepancy, only two of the patients being male, corresponded with the findings of earlier studies. The incidence was closely related to age, the disease being most frequent in adolescent girls and young women

(age group 14 to 25). Earlier observers, such as Déjerine and Gauckler (1911) had been so struck by this relation to sex and age that they reserved the term "primary anorexia" for that seen in adolescent girls and young women, while they postulated that forms seen at other ages were "secondary" to other mental disturbances. The relation of *anorexia nervosa* to known psychological trauma could be established in less than one-half of the cases; these were usually the younger patients, for whom there was a better prognosis. In the older, the intractable anorexia not associated with psychological disturbance led to progressively worsening asthenia.

The fact that the response of *anorexia nervosa* to corticotropin is sometimes favourable, both as regards restoration of appetite and regression of abnormalities of behaviour (Wolfson, 1954), is difficult to interpret in terms of etiology because of the possibility that corticoids have both peripheral and central effects on food intake. To this reviewer, *anorexia nervosa* may well be, like obesity, a collection of distinct entities, of which many are of regulatory nature, either psychogenic or hypothalamic, but some may prove to be metabolic.

MODE OF ACTION OF DIFFERENT TREATMENTS

We may now consider the physiological and pharmacological basis for the drugs, preparations and methods of treatment used to deal with obesity and anorexia. Drugs such as amphetamine, gossypol (Eagle and Bialek, 1950), sedatives, and methylcellulose preparations are regulatory agents; so are the prescribed rituals which are part of the armamentarium of certain healers and those who practise individual and group psychotherapy. Agents like thyroid, the notorious dinitrophenols, pills made of maltose or other sugars, and reducing diets are metabolic in their action, as are, in the treatment of extreme leanness, insulin, high-fat diet, and intravenous and oral fat emulsions. The effect of diethylthiocarbamate on mice with the obese hyperglycaemic syndrome also appears to be metabolic (Mayer *et al.*, 1953). As a rule, regulatory agents overrule metabolic factors. For example, amphetamine will counteract the appetite-enhancing effect of insulin. Agents acting on the gastro-intestinal tract (*e.g.*, "bulk" pills of methylcellulose) seem to have relatively little effect on the total daily intake although they strongly influence the size of individual meals. It may not be unreasonable to think that response to treatment with psychotherapy, corticotropin or insulin may provide clues to the primary etiology in different types of anorexia.

Vol. 25, No. 4

INTERACTION BETWEEN CONSTITUTIONAL AND ENVIRONMENTAL FACTORS, AS EXEMPLIFIED BY THE ROLE OF PHYSICAL ACTIVITY

The interrelation of the effects of constitution and diet on bodyweight has been discussed above. Recognition of this relation is shown in the endless quest for more successful reducing (or fattening) diets. The importance of constitutional factors and of environmental temperature has been alluded to. The problem of the relation of exercise to bodyweight is of major theoretical and practical importance; yet in the past one or two decades, at least on the western side of the Atlantic, the role of exercise in weight control has been minimised, if not ridiculed, and exercise has been denied any part in "obesity" programmes. This denial has not been based on recent experimental or clinical work or on the accumulated experience of centuries, which has always contrasted the lean, hard, active soldier or hunter with the fat merchant or clerk. Two plausible misconceptions have dominated the field:

- (1) Exercise requires relatively little calorie expenditure and therefore increased physical activity hardly changes the calorie balance.
- (2) An increase in physical activity is *always* automatically followed by an increase in appetite and food intake and may therefore actually impair weight reduction.

Let us examine these two propositions.

ENERGY EXPENDITURE IN EXERCISE

The first misconception, which minimises the calorie expenditure due to physical activity, should be avoided by anyone who has ever looked at a table of energy expenditure. Such tables clearly show that the cost of exercise can be high. For example, the table of recommended dietary allowances of the Food and Nutrition Board, U.S. National Research Council (1953) gives calorie values for men ranging from 2400 to 4500 Cal. daily according to the level of activity. The figure of 4500 Cal. daily does not represent an upper limit; labourers, soldiers in the field and athletes often require up to, or even more than, 6000 Cal. daily.

In contrast with these statements, one frequently hears or reads such statements as the following: the calorie equivalent of a pound of fat can be matched only by walking for thirty-six hours, splitting wood for seven hours, or playing volley ball for eleven hours. These unattainable extremes of physical activity are used to demonstrate that it is impossible to lose weight by exercise. The implicit postulate is that the cost of exercise

depends entirely on the exercise being done at one stretch. Actually, of course, the cost of splitting wood for seven hours will still be equivalent to one pound of fat even though the seven hours may not constitute one stretch. Thus, while splitting wood for seven consecutive hours would be difficult for anyone other than a Paul Bunyan, splitting wood for half an hour every day, by no means an impossible task for a healthy man, would add up to seven hours in a fortnight. If it represented a regular practice, it would, by the very reasoning of the detractors of exercise, represent the calorie equivalent of 26 pounds of body fat in a year. Half an hour of handball or squash daily would be equivalent to sixteen pounds in a year.

It seems more useful, however, to recall the measured costs of different types of physical exercise. Orr and Leitch (1937-38), who had assembled their own and other workers' data (Cathcart and Orr, 1919; Kestner, 1923; Medical Research Council, Committee upon Quantitative Problems in Human Nutrition, 1924; Kestner and Knipping, 1928; Farkas and Geldrich, 1930; Maisels *et al.*, 1935; Moss, 1935; Rose, 1935) give values for the cost of different types of activity established for a "mean" man with a body surface of 1.77 sq. m., which corresponds, for example, to a height of 172 cm. (5 ft. 7 in.) and a weight of 65 kg. (143 lb.). The values are given as excess requirement per hour of work over basal rate, with a ten per cent. addition for specific dynamic action, so that they could be used directly for the calculation of requirements by the factorial method.

From these data, one can readily calculate that, for the mean man, examples of energy expenditure over the cost of sitting are: walking, 100 to 550 Cal. per hour, depending on the speed; swimming, up to 685 Cal. per hour; climbing, up to 885 Cal. per hour; skating, up to 685 Cal. per hour; and cycling, up to 585 Cal. per hour. These hourly rates of energy expenditure above the sitting level do not include the admittedly brief peaks of activity reached in competition, when calorie expenditures may approach 22 Cal. per minute. An expenditure of from 500 to 600 Cal. per hour above the resting level represents a rate of physical activity which can be endured by the average adult not in training for a period of thirty minutes without undue discomfort.

In most types of exercise, no heavy object is moved other than the whole or parts of the body. Therefore, the energy cost of exercise is proportional to bodyweight (Food and Agriculture Organization of the United Nations, 1950; Keys, 1949-50). If excess bodyweight is so great that it impairs body movement, the relationship will no longer strictly apply, and the cost of exercise will actually increase faster than bodyweight (Newburgh, 1944).

If the energy cost of exercise is approximately proportional to bodyweight, it follows that the overweight person will require more energy, and hence burn more body reserves, for the same amount of exercise, than a slimmer person would. Twenty per cent. overweight will increase the cost of walking, tennis playing, golfing and so on by twenty per cent. This represents a much greater proportional increase than that introduced by the increase in basal metabolism due to excess weight, which is proportional to only a fractional power of the bodyweight (Food and Agriculture Organization of the United Nations, 1950).

Thus, any increase of the calorie intake above balance level in a physically active person will cause only a modest increase in weight because of the energy cost of moving the extra poundage. On the other hand, in a sedentary person, less energy will be expended in moving the extra weight and hence weight gain will be more rapid and more pronounced. A sedentary person will therefore be exposed to the danger of overweight to a much greater extent than a person who makes a practice of daily, or at least frequent, physical exercise.

EXERCISE AND EXPERIMENTAL OBESITY

Results of studies of experimental obesity support these concepts. In the hereditary obese-hyperglycaemic syndrome, as has already been mentioned, the bulk of the extra energy comes from inactivity rather than from hyperphagia. If non-fasted animals are placed in activity cages and spontaneous activity is measured, it is found that non-obese animals are over 50 times as active as obese animals (Mayer, 1953a, b). Inactivity is not the result of extreme obesity but in fact precedes it, as is shown by the comparison of activity rates of mature non-obese animals and of young obese animals of the same weight. It can thus be considered as one of the etiological factors in the syndrome determined by the obese-hyperglycaemic gene. Non-obese animals remaining steady in weight consume about 20 Cal. daily, of which 10 cover basal expenditure and 2 cover specific dynamic action, leaving 8 for the cost of activity. Obese littermates consume about 25 Cal., and may gain up to 1 g. (or 9 Cal.) daily. Their basal expenditure again accounts for 10 Cal. daily and specific dynamic action for 2.5 Cal. daily. When the 8 Cal. expended daily on activity by the non-obese mouse are devoted in the obese mouse to fat synthesis, the rapid development of extreme adiposity is no longer a thermodynamic impossibility.

The weight gain of genetically obese mice can be drastically reduced by treadmill exercise (Mayer,

1955a). The obese members of the strain which carry the "waltzing" gene and are in constant rotary movement in their cages show a weight gain only about 30 per cent. greater than the non-obese mice, against 200 or 300 per cent. shown by the sedentary obese mice.

Hypothalamic obesity in the mouse is also characterised by a considerable degree of inactivity (Mayer, French *et al.*, 1955). In contrast, goldthioglucoase obese mice are normally active but will spontaneously lose weight if made to exercise more in a squirrel type of rotating cage (Marshall and Mayer, 1954). Such findings emphasise both the different degree of spontaneous activity in the different forms of obesity and the importance of exercise as a weight-controlling factor.

EXERCISE, FOOD INTAKE AND BODYWEIGHT

A frequent misconception about the value of exercise in weight control is that an increase in physical activity *always* causes an increase in appetite and food intake which equals, or is greater in energy value than, the energy cost of the exercise.

That in a normal, reasonably exercised animal or person an increase in food intake follows an increase in activity is true; it explains why the weight of most adult animals and men is relatively constant. Proper adjustments of appetite prevent the body from indefinitely burning away its reserves if called upon to exert itself at higher levels than those to which it has been accustomed. Experimental results, however, show that such an adjustment occurs only within a certain range, which has been termed by Mayer "normal activity range" (Mayer, 1954b; Mayer *et al.*, 1954).

EXERCISE AND WEIGHT IN EXPERIMENTAL ANIMALS

Early work (Gasnier and Mayer, A, 1939) had shown that rabbits, when restricted in their activity by confinement in a small cage, will consume more food than they require and accumulate fat. The excess food consumed is characteristic of the strain; hence a hereditary factor is involved here. The same phenomenon is illustrated by the fact that rats can be made obese by total immobilisation (Ingle, 1949).

The dependence of food intake and bodyweight on physical activity has since been systematically studied in experimental animals (Mayer *et al.*, 1954). When mature rats accustomed to a sedentary (caged) existence were exercised on a treadmill for increasing daily periods, it was observed that with moderate exercise for a short time (20 minutes to 1 hour) there was no corresponding increase in food

intake, which actually decreased slightly but significantly. Bodyweight also decreased ("sedentary range"). With longer periods of exercise (1 to 5 or 6 hours), food intake increased linearly and weight was maintained ("range of proportioned response", or "normal activity range"). With very long periods of exercise, the animals lost weight, their food intake decreased and their appearance deteriorated ("exhaustion range"). Both the sedentary and the exhaustion range can thus be considered "non-responsive" ranges with respect to food intake, since in them an increase in activity is not accompanied by a corresponding increase in food intake. The sedentary range is obviously of particular interest for the problem of obesity. It demonstrates that under abnormal environmental conditions which force on the subject partial immobilisation or at least a sedentary life, the limit below which the regulation of food intake no longer responds to a decrease in activity is overtaken. Obesity is the unavoidable result. This, of course, has been known empirically to farmers for centuries and explains the practice of penning or cooping up cattle, pigs and geese for fattening.

EXERCISE AND WEIGHT IN ADULT MAN

Similar observations are available on man. Greene (1939) has studied more than 200 overweight adult patients in whom the beginning of obesity could be traced directly to a sudden decrease in activity. Mayer has examined the relation of bodyweight to food intake and work in an industrial population of West Bengal (India) with a particularly wide range of physical activity, from bazaar tailors and clerks to coolies carrying twice their bodyweight on their heads for 9 hours. Fig. 1 (p. 878) illustrates the findings (Mayer, 1955b; Mayer, Roy and Mitra, in press). Ascertainment of food intake was easy, since most of the persons studied did not live in a family but bought their food and cooked it for themselves. The lack of provision for storage of food forced them to shop frequently. The diet was extraordinarily uniform for each individual and showed little variety within groups or from group to group. Individual records made each day of the food eaten, verified by records of the food bought and checks on the amount of money spent per week on food, gave results generally identical with exhaustive dietary histories and apparently more representative of the intake over a long period than corresponding data obtained in a western society. Activity was ascertained from detailed schedules, "expert" appraisal of physical effort and some Douglas bag measurements. Clerks were subdivided into 4 classes according to the mileage

walked daily to and from work, class one, who actually lived within the factory grounds, being the most inactive group. Each of the occupations or subgroups was represented by at least 10 subjects; they were classified according to degrees of activity, extremes being represented on the one hand by merchants, supervisors and "non-walking"

BODYWEIGHT AND CALORIE INTAKE AS A FUNCTION OF PHYSICAL ACTIVITY

FIG. 1.—The relation of intake and weight to exercise in an industrial male population in West Bengal (Mayer, 1955b).

clerks, at the other end by selectors and pilers, carriers who carried up to 190 pounds of jute per man, coalmen, ashmen who carried equally heavy bags of coal and ashes and unloaded them in an awkward manner, and cutters who spent their whole day swinging heavy cutting knives with scarcely any pause. The individual bodyweight ranged from 67 to 198 lb. for about the same height (5 ft. 2 in. to 5 ft. 4 in.). Economic differences and cultural, religious and ethnic factors were studied and ruled out in the analysis of the

results. It is readily seen from Fig. 1 that the results obtained for food intake, and for bodyweight as a function of food intake, are strikingly similar to those obtained with rats. Again, there is a sedentary range which corresponds to no further decrease in food intake, but, instead, to an increase, and where increasing degrees of overweight follow decreasing exercise. The meaning of the actual increase in food intake under extremely sedentary conditions is, however, not clear. It may indicate a decrease in the availability of reserves, possibly from circulatory sluggishness due to inactivity.

EXERCISE AND WEIGHT IN CHILDREN

The problem of the relation of weight to activity in children has been investigated also. Bruch (1940) found that inactivity was characteristic of most of the 160 obese children whom she had studied. Only 18 per cent. of the boys and 22 per cent. of the girls were "normally" active. Seventy-six per cent. of the boys and 68 per cent. of the girls were physically inactive. Rony (1940) suggested that laziness or decreased tendency to muscular activity is a primary characteristic of obese subjects; in childhood it is demonstrated by avoidance of all unnecessary activity, outdoor play and athletics. Bronstein *et al.* (1942) found that most of the 35 obese children whom he and his associates studied spent much of their leisure time in sedentary activities. Graham (1947) reported similar observations. Danish workers, in particular Tolstrup (1953) and Juel-Nielsen (1953), attempted a semi-objective grading of groups of obese children and found that lack of activity was characteristic of them. Peckos (1953), studying a large group of Boston children, found that differences in body build, and more specifically in fat content and distribution, were not correlated with calorie intake. Fry (1953), studying obese children selected as presenting large fat pads, found that they did not have higher average calorie intakes than non-obese children of the same height and age. In her "rough psychological evaluation" a much higher proportion of obese than of non-obese children is labelled as inactive or only moderately active. The difference was particularly marked in boys. No data, however, are given to support her estimate.

In a recent study, Johnson *et al.* (in press) attempted to compare calorie intake and activity in carefully paired groups of obese and normal-weight schoolgirls. Exhaustive dietary histories and activity schedules covering the year preceding the study were obtained. The research method of Burke (1947) was used, in particular regard to the difficulties encountered in relation to children (Mayer, 1952) and to obese children (Beaudoin and Mayer, 1953; van der Meer, 1954).

Mayer, 1954). The schedule of physical activity was obtained by a system of successive examinations. First a list of usual activities was established and the subjects were asked how much time they devoted to each, on a daily or weekly basis, depending on the type of activity considered. The subjects were then asked to complete the list of activities and schedules, covering the year by seasons. Total hours per week were checked, and in another interview the activities were re-checked on the same general basis. If the total time per week had been grossly over- or underestimated, special efforts were made to find out the causes of the error. The activities were rated by the method of Rose (1935) and Orr and Leitch (1937-38). It was found that suburban high-school girls were generally not very active. Even the schedules of the non-obese group showed little time devoted to household duties, little participation in active sports and, at least during the school term, a minimum amount of time devoted to walking or to other physical activity. Even so, however, there was a marked difference between the obese and non-obese groups. The obese group was much more inactive than the non-obese. In general, the time spent by the obese group in sports or any sort of exercise, including ballroom dancing, was less than half that spent by the thin girls, the difference being absorbed by "sitting" activities. In contrast, calorie intakes were generally larger in the non-obese group than in the obese. When possible factors leading to positive energy balance are analysed, it appears therefore that in this particular obese group, even though probable sources of error inherent in the dietary interview method and in the type of activity analysis selected are recognised, inactivity was of greater importance than overeating in the development of obesity. The importance of exercise as a weight-controlling factor in this population of high-school girls was emphasised by the fact that when obese and non-obese girls attended summer camp, almost without exception they reported loss of weight under the system of enforced strenuous activity, in spite of a simultaneous increase in food consumption.

CONSTITUTIONAL FACTORS, EXERCISE AND WEIGHT

The following conclusions appear to be supported by the evidence presented above. First, it is trite but perhaps useful to say that exercise is the major variable in energy expenditure. Secondly, there is a sedentary range in which a decrease of activity is not followed by a decrease of food intake and the subject accumulates fat. Constitutional factors determine the extent of this range as well as the

magnitude of the effect of immobilisation. There is also a "non-responsive" range at high activity levels, its limit being again determined by constitution. Finally, though enforced exercise can move a person from the sedentary range to the range of normal activity, constitution will determine whether the subject, given a suitable environment, will spontaneously step up his activity so that he leaves the sedentary range. Thus it becomes apparent that the regulation of food intake, even in a normal subject, has a limited range of effectiveness as regards response to physical activity, and that environmental conditions can bring about regulatory disturbances leading to relative hyperphagia or to calorie deficit. The size of the effective range determines the capacity for adaptation. Beyond the limits of adaptation are regulatory obesity brought about by immobilisation and regulatory excessive leanness brought about by overwork. Again, the case, though of special practical importance, is but part of a general phenomenon.

CONCLUSIONS AND PRACTICAL SUGGESTIONS

COMPLEXITY OF THE PROBLEMS OF OBESITY AND EXCESSIVE LEANNESS

The aim of the reviewer has been to give the reader an idea of the extreme complexity of the problems set by obesity and excessive leanness. That there are inaccuracies and even serious errors in the picture drawn is highly probable; it can only be hoped that the inspiration of Montaigne's admonition has been heeded: "All of us, being human, are bound to err many times in our lives. The misfortune is not to be wrong; it is to be wrong pompously." In this field pompous generalisations and deceptively simple solutions have often been the rule: for example, it is quite obvious that if patients with anorexia can be made to add to their diet a quarter of a pound of butter, or the calorically equivalent quantity of fat emulsion, every day, they will put on weight. Similarly, legitimate belief in the validity of the first law of thermodynamics would dictate that any "low-calorie diet" should be effective in the treatment of obesity. Actually, the careful work of Kekwick and Pawan (1953) on weight loss in the obese, which included the study of water balance, nitrogen balance, creatinine and faecal fat, as well as some "compartment analysis" (distribution of body water), shows that while calorie restriction in the obese results in weight loss, the degree of weight loss does not appear to bear any simple relation to the degree of calorie deficiency, the rate

walked daily to and from work, class one, who actually lived within the factory grounds, being the most inactive group. Each of the occupations or subgroups was represented by at least 10 subjects; they were classified according to degrees of activity, extremes being represented on the one hand by merchants, supervisors and "non-walking"

CONCLUSIONS AND PRACTICAL SUGGESTIONS

COMPLEXITY OF THE PROBLEMS OF OBESITY AND EXCESSIVE LEANNESS

The aim of the reviewer has been to give the reader an idea of the extreme complexity of the problems set by obesity and excessive leanness. That there are inaccuracies and even serious errors in the picture drawn is highly probable; it can only be hoped that the inspiration of Montaigne's admonition has been heeded: "All of us, being human, are bound to err many times in our lives. The misfortune is not to be wrong; it is to be wrong pompously." In this field pompous generalisations and deceptively simple solutions have often been the rule; for example, it is quite obvious that if patients with anorexia can be made to add to their diet a quarter of a pound of butter, or the calorically equivalent quantity of fat emulsion, every day, they will put on weight. Similarly, legitimate belief in the validity of the first law of thermodynamics would dictate that any "low-calorie diet" should be effective in the treatment of obesity. Actually, the careful work of Kekwick and Pawan (1953) on weight loss in the obese, which included the study of water balance, nitrogen balance, creatinine and faecal fat, as well as some "compartment analysis" (distribution of body water), shows that while calorie restriction in the obese results in weight loss, the degree of weight loss does not appear to bear any simple relation to the degree of calorie deficiency, the rate

and extent of weight loss varying greatly with the type of diet. Thus, in their patients, high-fat reducing diets led to greater weight loss than isocaloric high-carbohydrate reducing diets. Only a study of metabolism and energy expenditure, including "basal" and physical activity, could interpret these findings. Similarly, the difficulties encountered in practice when dealing with either obesity or thinness are better understood when the complexity of the factors regulating food intake is realised. Intermediary metabolism, and humoral, hormonal and autonomic regulations can be involved in metabolic disturbances, while environmental conditions, activity, social and cultural "milieus", and neurological and psychological factors may lead to regulatory disturbances. The existence of such a multiplicity of determinants logically leads one to avoid over-simplifications and universal cures.

The same multiplicity leads one to expect that different reactions to the same treatment may be expected in patients with obesity or excessive leanness. Of particular interest in this connection is the finding by Ohlson (1955) that obese patients losing weight for a sufficient period can be classified into two groups: those who can be maintained in nitrogen balance and those who are in negative nitrogen balance, even on high-protein reducing diets where calories are not too drastically curtailed. The first group present a fair prognosis as far as staying at the lower weight reached after treatment is concerned. The second group, in negative nitrogen balance, present an extremely poor prognosis and invariably return to the pre-reduction weight as soon as rigid control is removed. This physiological difference may correspond to the psychological classification attempted by Young (1955), who found that some of her patients could be put on reducing diets without manifesting any special emotional difficulties but another group deteriorated psychologically when their calorie intake was cut down. Finally, there is general agreement (Beaudoin *et al.*, 1953; Bruch, 1955; Stuart, 1955) that patients persistently obese since childhood constitute a distinct problem, more difficult than that of patients whose weight has fluctuated widely, including periods of normal weight, or patients who have become obese in adult life. These different types of classification, physiological, psychological, chronological, as well as those based on general anthropometric descriptions (*e.g.*, android, gynaeoid (Leroy, 1951)) and on descriptions of the number and distribution of adipose cells (Tanner, 1954) have yet to be combined in a comprehensive taxonomic system. In the long run, only identification of the cause of the primary condition and understanding of its mechanism will permit systematic and successful treatment.

PRACTICAL SUGGESTIONS CONCERNING OBESITY

The reviewer, in the course of several years during which he has given consideration to weight control programmes, has arrived at some practical suggestions which may be of use to readers engaged in treatment.

General Attitude of the Therapist. Obesity is not a moral issue. It is a medical problem, complex and little understood. Censorious comments, sermons, and the shifting of the entire responsibility on to the patient are neither proper nor effective.

Diagnosis of Obesity. Blind application of height-weight tables is unscientific. The principles underlying the construction of these tables have been ably criticised by Keys (1955). In practice, extreme deviations from the average are obvious. Smaller deviations cannot be interpreted without examination of the patient for muscle development. The old-fashioned pinching method is a cheap and simple substitute for underwater weighing, measurement of thiocyanate or deuterium space, and the like.

Inducements to the Patient. "Scare" propaganda is one of the curses of the modern world. Though the association of obesity with increased mortality and morbidity risks is established, distinction between association and causation is not always clear. There is enough evidence to justify reduction programmes to promote health as well as on aesthetic grounds, but there are dangers in threats as well as in excessive promises of reward. This has been particularly emphasised by Bruch (personal communication) as regards children.

Informing and Misinforming the Patient. It is necessary to inform the patient about the first law of thermodynamics, and about the calorie value of foods. The importance of the latter cannot be overemphasised. Sound knowledge of the calorie value of foods will not only guide the patient during treatment, it will also protect him against the dishonest claims of manufacturers of "miracle foods" (such as "low caloric bread"). It is wrong and dangerous to belittle the influence of genes or exercise.

Use of Hereditary Data. It has been repeatedly shown (see above) that obesity runs in families, with genetic as well as environmental factors involved. Studies in the United States have shown that less than 10 per cent. of the children of parents of normal weight are obese, but that the proportion rises to 50 per cent. if one parent is obese and to 80 per cent. if both parents are obese. Studies of identical and fraternal twins have shown that food habits are not the main factor. Instead of denying the facts of heredity it would be more intelligent and effective to use them to detect other overweight persons and, more im-

portant, to try to prevent the development of obesity in susceptible children. Obesity is most malignant when the onset is early.

Exercise. Natural selection, operating for hundreds of thousands of years, made men active, resourceful creatures, well prepared to be hunters, fishermen or farmers. The mechanism regulating food intake was not adapted to the highly mechanised conditions of modern life, any more than animals were evolved to live in a cage. In many cases, adaptation to modern conditions without development of obesity implies that the person will have either to step up his activity or endure mild or acute hunger all his life. The first alternative is difficult, especially in the United States and Canada, where the cities offer little inducement to walking and are often poorly provided with facilities for adult exercise. Even among the young, highly competitive sports for the few are often emphasised at the expense of individual sports which all could learn and continue to enjoy after school and college years are over. If the first alternative, stepping up activity, is difficult, it is well to remember that the second alternative, life-time hunger, is so much more difficult that to rely on it for weight control in cases of sedentary overweight can only continue to produce the fiascos of the past. Strenuous exercise on an irregular basis, in untrained persons already obese, is obviously not what is advocated here. But a re-organisation of one's life to include regular exercise adapted to one's physical capacity is a sound preventive measure and a justified return to the wisdom of the ages. Moderate exercise during weight reduction, when practicable, also helps in promoting nitrogen balance and muscle tone.

Diets. The essential principle to follow in devising the diets is that a good reducing diet is one on which the patient does not feel too hungry. The diversity of probable etiologies makes it likely that different patients will feel more comfortable on different types of diet. In practice, the choice of foods by obese individuals and their feeding patterns are as diverse as in normal subjects (Beaudoin and Mayer, 1953). It has been repeatedly found (Beaudoin and Mayer, 1953; Dole *et al.*, 1954; Stunkard, Grace and Wolff, 1955) that most obese patients tend to do their overeating late in the day and at night, which indicates that evening eating should be controlled with particular care. Diet prescription should be an individual operation, adapted to the patient's rate of energy expenditure and desired rate of weight loss. It should furnish an opportunity for education in the caloric value of foods. It should also permit nutrition education in general. Finally, it should be experimental; trial and error will permit the finding of the most effective diet, as well as the most suitable schedule of exercise. "Fad" diets

may have a short-term value but they have no lasting educational or practical worth. If, as some have claimed, it is possible to "shrink the stomach" or "re-train the appetite", special diets might perhaps be used for that purpose before a change is made to a more normal diet. The evidence offered in favour of the process is, however, very scanty. In some cases, better success is obtained with smaller and more frequent meals. The practice of eating slowly seems desirable on physiological grounds, since satiety mechanisms are likely to need time to take effect; it is desirable on psychological grounds also.

Obesity in Childhood and Pregnancy. It seems undesirable as a rule to attempt to reduce weight in children or pregnant women. A better solution consists in keeping the child's weight at its existing value and letting the child "grow up" to the weight, and in letting *post partum* weight loss achieve at least part of the desired result in the woman. It is important to remember, when dealing with obesity in childhood, that inactivity may be the major cause and that it may be easier and more effective to step up activity than to reduce food intake. Care must be exercised, particularly with children obese since their youth, not to do more harm than good; with present methods, the prognosis for such subjects is generally poor and the psychological trauma of persistent and tactless attempts at reduction may be considerable.

Limitations of Potential Success. It ought to be more generally recognised that present-day methods are ineffective with many individuals. With some patients, psychiatrists feel that attempts at weight reduction may be undesirable in the absence of a complete physiological and psychological investigation which may be out of the question. It has already been mentioned how Ohlson (1955) showed that a certain type of obese patient is invariably thrown into negative nitrogen balance on reducing diets, even of the high-protein variety, and that the weight of this type of obese patient returns rapidly to its original level when the period of treatment is over. In general, few problems are more important in this field than the typing of obese patients as regards their anthropometric, metabolic and psychological characteristics. Modes of response to different treatments are doubtless highly correlated with the precise nature of the abnormalities.

Note added in proof. Since this review was written, a number of reports have confirmed, extended and interpreted previous findings. Stunkard, Van Itallie and Reis (1955) have reported that glucagon abolishes hunger contractions and subjective hunger. It simultaneously raises blood glucose and increases capillary-venous differences. Subsequent fall in blood glucose levels with decreasing capillary-venous differences is associated with a

return of hunger contractions and intensification of the experience of hunger. A technique has been developed by Larsson and co-workers (1955) for recording encephalograms from the "feeding" areas. Souleirac's finding of an association between hyperphagia and increased intestinal absorption of glucose in hypothalamic obese rats (Part 1, p. 604) has been extended to hypothalamic obese mice, goldthiogluconase obese mice and genetically obese-hyperglycaemic mice (Mayer and Yanonni, 1955, in press). The increased absorption has been shown to be probably secondary to the excessive consumption of high-carbohydrate diets, with no primary etiological significance. The metabolic nature of the obesity in mice resulting from the graft of tumours secreting adrenocorticotrophic hormone has been established (Mayer, Zomzely and Furth, 1955, in press). This syndrome also entails

increase of body cholesterol. It has been shown that goldthiogluconase, but not goldthiomalate or other goldthio-compounds which are equally toxic, causes severe lesions in the ventromedial ("feeding") area of the hypothalamus (Marshall *et al.*, 1955, in press). The lesions are permanent in animals which become obese. The area damaged is that previously postulated by Mayer to contain glucoreceptors and shown by Forssberg and Larsson to concentrate phosphate and glucose in the fasted state (p. 605). The suggested etiology of the obese-hyperglycaemic syndrome has been supported by the finding of a sixfold increase in pancreatic glucagon after growth hormone administration (Clarke *et al.*, to be published); these animals show also an increased glycogen turnover and increased liver phosphorylase activity (Shull and Mayer, 1955, in press).

I. TECHNIQUE

CHEMICAL

APPARATUS

4521

GROGAN, C. H. and ROBOZ, E. Simple apparatus for concentrating biologic fluids of low protein content. *J. Lab. Clin. Med.*, 1955, **45**, 495-498. [Nat. Cancer Inst., Dept. Health, Bethesda, Md.]

A dialysis apparatus is described.—H. G. Bray.

4522

BROWN, J. H. U. and BAIN, J. A. A simple Warburg calibrator. *J. Lab. Clin. Med.*, 1955, **45**, 822-824. [Dept. Physiol., Emory Univ., Ga.]

The device which is described makes possible the calibration of vessel and manometer in a single operation.—H. G. Bray.

4523

COOK, C. D., CHERRY, R. B. and KARLBERG, P. An adaptation of the capillary pH electrode for practical use. *Pediatrics*, 1955, **15**, 200-201. [Boston Lying-in Hosp., Mass.]

A simple suction system is attached to the capillary electrode to allow easy filling and rinsing in routine analysis. The electrode was used for plasma and blood of infants and small animals.

H. G. Bray.

4524

FRANGLIN, G. T., MARTIN, N. H. and TREHERNE, J. D. An apparatus for paper electrophoresis. *J. Clin. Pathol.*, 1955, **8**, 144-149. [Dept. Chem. Pathol., St. George's Hosp. Med. Sch., London.]

The relatively complex apparatus designed meets the 3 requirements considered essential. Stable electrical conditions were produced by the use of reversible Ag—AgCl—KCl electrodes. The horizontal filter-paper strip was kept in stable condition by the even distribution of buffer, controlled tension and the reduction to a minimum of changes in temperature and water vapour pressure. The material to be analysed was applied to the filter paper with the minimum disturbance by a micrometer syringe through a tiny hole in the lid of the air-tight box containing the apparatus. Electrophoresis can proceed in the presence of gases other than air. The cost of the apparatus was considered to be offset by the highly reproducible results obtained.—A. Hepburn.

4525

MEAD, T. H. Apparatus and technique for two-dimensional paper ionophoresis. *Biochem. J.*, 1955, **59**, 534-543. [S. African Coun. Sci. Indust. Res., Cape Town.]

ANALYTICAL METHODS

General

4527

PINTA, M. Applications de la spectrographie de flamme et d'arc dans l'analyse agronomique. [Applications of flame and arc spectrography in agricultural analyses.] *Ann. agronom.*, 1955, **6**, 189-202. [Lab. Spectrograph., Inst. Enseignement Recherches Trop., Bondy.]

4528

MATCHETT, J. R. and LOESECKE, H. W. v. Review of industrial applications of analysis, control, and instrumentation. *Food. Anal. Chem.*, 1955, **27**, 623-632. [Washington Utilization Res. Branch, Agric. Res. Serv., U.S. Dept. Agric., Washington, D.C.]

A review of recent work on estimation of moisture, proteins and amino-acids, metallic ions, fats and oils, enzymes, carbohydrates, vitamins, acids, colour and taste.

4529

ARCHIBALD, R. M. Review of industrial applications of analysis, control, and instrumentation. *Clinical chemistry. Anal. Chem.*, 1955, **27**, 677-679. [Hosp. Rockefeller Inst. Med. Res., New York 21.]

A review of some recent contributions to quantitative clinical chemistry.

4530

CERIOTTI, G. A simple paper chromatographic technique for the study of free metabolites of tissues and body fluids. *Nature*, 1955, **175**, 897-898. [Centro Tumori, Busto Arsizio, Varese, Italy.]

The filter paper is held between 2 glass plates, one of which has a small central hole. The tissue is dried at 100° C., powdered and evenly

distributed in the hole and held in place by a filter-paper disk. The plates are then inverted over the developing solvent so that the chromatogram can be irrigated by a wick.—H. G. Bray.

4531

GANGULI, N. C. A relation between R_F values of unidimensional and circular paper chromatography. *Anal. chim. Acta*, 1955, **12**, 335-341. [Dept. Appl. Chem., Univ. Coll. Sci. Technol., Calcutta.] French and German summaries.

The squares of the circular R_F values of the amino-acids and sugars studied were observed to be equal to the linear R_F values. This relation can be accounted for theoretically.—H. G. Bray.

4532

BICKEL, H. Die klinische Bedeutung der Papierchromatographie für die Entdeckung von Aminosäuren und Zuckerstoffwechselstörungen. [The clinical use of paper chromatography to detect disorders of amino-acid and sugar metabolism.] *Helv. paediat. Acta*, 1955, **10**, 258. [Kinderklin., Univ. Marburg.]

Carbohydrate Constituents

4533

GLEGG, R. E. and EIDINGER, D. A method for fractionating the carbohydrate components of bone. *Arch. Biochem. Biophys.*, 1955, **55**, 19-24. [Dept. Anat., McGill Univ., Montreal.]

A neutralised NaOH extract of cattle bone shavings was fractionated by precipitation with 63 and 84 per cent. ethanol. From paper chromatograms of the hydrolysates one fraction was found to contain glucuronic acid and galactosamine and was therefore tentatively identified as chondroitin sulphate. The other fraction contained fucose, galactose, mannose and glucosamine.

A. Hepburn.

4534

TÄUFEL, K. and MÜLLER, K. Die Reversion der Saccharide und ihre Bedeutung für die Analytik der Kohlenhydrate. 1. Zum Chemismus der Reversion. [The reversion of sugars and its importance in analysis of carbohydrates. 1. The chemistry of reversion.] *Ztschr. Lebensmittel-Untersuch. Forsch.*, 1955, **100**, 351-359. [Inst. Ernährungsforsch., Potsdam-Rehbrücke.]

The reversion on heating of solutions of *d*-glucose, *d*-galactose, *d*-mannose, *d*-fructose, *l*-sorbose, *l*-arabinose and *d*-xylose was studied analytically and chromatographically, with different concentrations of sugar and HCl.—D. Duncan.

4535

BRÜCKNER, J. Estimation of monosaccharides by the orcinol-sulphuric acid reaction. *Biochem. J.*, 1955, **60**, 200-205. [Chem. Sect., Dept. Pathol., Univ. Otago Med. Sch., Dunedin.]

The measurement of the absorption spectra of a 31.2 N H_2SO_4 -orcinol-monosaccharide solution after a 50-sec. immersion in boiling water enabled individual monosaccharides to be characterised and estimated either singly or in binary mixtures.

A. Hepburn.

4536

VENNER, H. Eine Schnellmethode zur papierchromatographischen Bestimmung reduzierender Zucker. [A rapid method for estimating reducing sugars by paper chromatography.] *Naturwissenschaften*, 1955, **42**, 179-180. [Inst. Mikrobiol., Jena.]

Circular paper chromatography is used, with a mixture of butanol, acetone, ammonia and water (40 : 50 : 3 : 15) as solvent and aniline phthalate as spray reagent.—H. G. Bray.

4537

FISCHER, F. G. and DÖRFEL, H. Die quantitative Bestimmung reduzierender Zucker auf Papierchromatogrammen. [Quantitative estimation of reducing sugars by paper chromatography.] *Hoppe-Seyler's Ztschr.*, 1954, **297**, 164-178. [Chem. Inst., Univ. Würzburg.]

4538

FISHER, H., HANSEN, R. G. and NORTON, H. W. Quantitative determination of glucose and galactose. *Anal. Chem.*, 1955, **27**, 857-859. [Univ. Illinois, Urbana.]

Glucose and galactose were simultaneously estimated in mixtures by a modification of Brückner's method (*Hoppe-Seyler's Ztschr.*, 1941, **268**, 163) in which orcinol and concentrated H_2SO_4 reacted with the sugars and colour developed. The reaction took place in the spectrophotometer tube and from the absorbance at 470 and 560 m μ . standard equations were derived from which the amounts of the sugars in unknown mixtures were calculated. Results were usually within 0.03 mg. for glucose and 0.01 mg. for galactose in amounts up to 0.150 mg. of each sugar.

A. Hepburn.

4539

LEVY, R. Perfectionnement à la méthode de Folin de mesure de la glycémie. [Improvement of Folin's method of estimating blood sugar.] *Méd. trop.*, 1954, **14**, 734-740. [Corps de Santé Colonial.]

The final colour developed when the original method was used was found to vary in repeated estimations of the same sugar solution and did not follow the Beer Lambert law exactly. The diffi-

N.A. and R., October 1955

culty was overcome by making 2 changes in the technique. The tubes were cooled after removal from the water-bath and before the phosphomolybdic-tungstic reagent was added. After addition of the reagent and when gas had ceased to come off, the tubes were heated again for 5 min. in a boiling-water bath before the solution was diluted for the colorimetric or photometric estimation of the sugar.—L. Wills.

4540

VOLLAIRE-SALVA, J. L'analyse du glucose industriel. [Analysis of industrial glucose.] *Mitt. Geb. Lebensmittel. Hyg.*, 1955, **46**, 58-66. *Proc.* [Paris.]

4541

NAGHSKI, J., WILLITS, C. O. and PORTER, W. L. Maple sirup. 8. A simple and rapid test for the analysis of maple sirup for invert sugar. *Food Res.*, 1955, **20**, 138-143. [E. Reg. Res. Lab., Philadelphia 18, Pa.]

For previous work see Abst. 3378, Vol. 25.

An approximation to within 1 per cent. of the invert sugar content of maple syrup was obtained from the colour reaction of a series of dilutions after the addition of "Clinitest" tablets.—A. Hepburn.

4542

CHEFURKA, W. Some observations on the determination of fructose by the Seliwanoff reaction. *Analyst*, 1955, **80**, 485-486. [Sci. Serv. Lab., Canada Dept. Agric., Univ. Sub Post Office, London, Ont.]

A calibration curve obeying Beer's law can be obtained if sufficient time is allowed for maximum colour development to occur.—H. G. Bray.

4543

WHITE, L. M. and SEOR, G. E. Microscopic identification of microgram quantities of D-fructose. Direct synthesis of crystalline 2,4-dinitrophenylhydrazones by solvent diffusion technique. *Anal. Chem.*, 1955, **27**, 1016-1018. [W. Utilisation Res. Branch, Agric. Res. Serv., U.S. Dept. Agric., Albany 10, Calif.]

As little as 0.5 μ g. of pure fructose or 10 μ g. of that separated by chromatography can be identified by the formation of its 2:4-dinitrophenylhydrazone dioxane solvate. Some other sugars give less sensitive and rapid reactions; many give no apparent reaction under the conditions described.—H. G. Bray.

4544

GIBBONS, M. N. The determination of methylpentoses. *Analyst*, 1955, **80**, 268-276. [Lister Inst., London, S.W.1.]

Vol. 25, No. 4

4545

BÖHM, P. and RICHARZ, G. Zur quantitativen Bestimmung von Inosit in Phosphatiden. [Quantitative estimation of inositol in phosphatides.] *Hoppe-Seyler's Ztschr.*, 1954, **298**, 110-120. [Med. Klin., Univ. Bonn.]

The lipid is hydrolysed in a sealed tube with 6N HCl at 110°C. for 6 hr. and the inositol is separated by paper chromatography with a mixture of isopropanol, acetic acid and water (3:1:1) as solvent and elution with water. The inositol in the eluates is estimated by a periodate oxidation method.—H. G. Bray.

4546

DOUGALL, H. W. Correction of 'crude-fibre' estimation for the effect of altitude. *Nature*, 1955, **175**, 952. [Sch. Agric., King's Coll., Univ. Durham.]

The crude fibre in material analysed at 5700 ft. was inversely related to the logarithm of the digestion time. A formula is given by which the digestion time, which has to be increased at higher altitudes beyond the conventional 30 min. at sea level, is calculated from the boiling-point of the reagents. Alternatively, another formula enables a correction to be applied to the crude fibre obtained after digestion for 30 min.—A. Hepburn.

4547

GAILLARD, B. D. E. Chromatografisch onderzoek naar de samenstelling van de polysacchariden uit de celwand in verband met de analyse van ruwvoerders. [Chromatographic study of the composition of the polysaccharides of the cell wall, with reference to the analysis of coarse fodders.] *Meded. Landbouwhogeschool, Wageningen*, 1954, **54**, 115-179.

See Abst. 1584, Vol. 25.

Nitrogenous Constituents

4548

GRUNBAUM, B. W., KIRK, P. L., GREEN, L. G. and KOCH, C. W. Kjeldahl method with sealed tube digestion. Factors influencing ammonia decomposition. *Anal. Chem.*, 1955, **27**, 384-388. [Dept. Biochem., Univ. California, Berkeley 4.]

Loss of ammonia in the sealed tube procedure was shown to be due to its oxidation to nitrogen.

H. G. Bray.

4549

SHER, I. H. Two-step mixed indicator for Kjeldahl nitrogen titration. *Anal. Chem.*, 1955, **27**, 831-832. [Dept. Chem., Mount Sinai Hosp., New York 29.]

A mixed indicator of bromocresol green, new coccine and p-nitrophenol gave a sharp end-point

in the acid titration of ammonia trapped in boric acid solution.—A. Hepburn.

4550

ADAMS, C. I. and SPAULDING, G. H. **Determination of organic nitrogen by Kjeldahl method without distillation.** *Anal. Chem.*, 1955, **27**, 1003-1004. [Dept. Chem., Morgan State Coll., Baltimore, Md.]

The catalyst used for digestion is selenium. It is removed by precipitation with sulphurous acid; the excess of this is boiled off and the ammonia is estimated by formol titration.—H. G. Bray.

4551

BEET, A. E. **Potassium permanganate in the Kjeldahl method for the determination of nitrogen in organic substances.** *Nature*, 1955, **175**, 513-514. [Dept. Fuel Technol., Univ. Sheffield.]

4552

MAYER, S. W., KELLY, F. H. and MORTON, M. E. **Ammonia determination and sample preparation for mass spectrometer by a micro diffusion method.** *Anal. Chem.*, 1955, **27**, 837-838. [Radioisotope Unit, Veterans Admin. Hosp., Long Beach, Calif.]

A sealed 30-ml. bottle with the N-containing material and concentrated K_2CO_3 was rotated at $65^\circ C$. The NH_3 liberated was absorbed in H_2SO_4 suspended above the alkaline sample in glass "helices" on a glass rod passing through the stopper. The H_2SO_4 was transferred to a solution of Nessler's reagent and the NH_3 was estimated by spectrophotometer. The method is suitable for large numbers of routine microanalyses. From 0.5 μg . to 10 mg. N can be measured. It is also very satisfactory for the estimation of isotope ratio with a mass spectrometer after converting the NH_3 to N with hypobromite.

A. Hepburn.

4553

LEFEBVRE, J. M. **Les constituants azotés solubles chez les végétaux (méthodes d'étude).** [Soluble nitrogenous constituents in plants (methods of study).] *Ann. agronom.*, 1954, **5**, 995-1007. [Lab. Plantes Fourragères, Rouen.]

The preparation of samples of plant material for the extraction of the soluble nitrogenous constituents and their analysis are described. Standard methods of analysis were used with modifications where desirable. The analysis for protein N, total soluble N, polypeptide N, N from the trichloroacetic acid precipitation, free ammonia, nitrate, total and unstable amide N and total amino-N and the separation of the amino-acids of the soluble N fraction are described. Results of

varying accuracy were obtained. Colorimetric estimation of amino-acids was accurate to within 4 per cent. Total soluble N and protein N were accurate to 1 or 2 per cent., but ammonia and nitrate were less accurate, and amide N, polypeptide N and total amino-N were the least accurate.

JENCKS, W. P., JETTON, M. R. and DURRUM, E. L. Paper electrophoresis as a quantitative method. Serum proteins. *Biochem. J.*, 1955, 60, 205-215. [Dept. Pharmacol., Army Med. Serv. Grad. Sch., Walter Reed Army Med. Centre, Washington, D.C.]

The quantity of bromophenol blue bound by denatured serum proteins after electrophoresis on filter paper depended on the time of heat denaturation, the time of staining and the amount of rinsing. Under the conditions described only the densely stained albumin fraction deviated from Beer's law when directly scanned. Albumin tailing amounted to only 3 to 5 per cent. of the total albumin and a correction could be applied for it. There was a linear relation between dye uptake and protein concentration which did not depend on the area of application of protein.

WIELAND, T., DOSE, K. and PFLEIDERER, G. **Eine enzymatische Bestimmung des Glutathions. [Enzymic estimation of glutathione.]** *Biochem. Ztschr.*, 1955, **326**, 442-445. [*Inst. Org. Chem., Univ. Frankfurt a. M.*]

In presence of glyoxalase I in phosphate buffer at pH 6.3 glutathione and methylglyoxal combine to form S-lactoylglutathione, which is measured spectrophotometrically by its ultraviolet absorption at 240 μ . The method and its application to human blood and mouse muscle and liver are described. As little as 15 μ g. glutathione can be estimated. The reaction is unaffected by previous treatment with trichloroacetic or perchloric acid, or by borate or Na ions, but cysteine is unsuitable as a reducing agent.—W. M. Deans.

4569

BAUDET, P. and CHERBULIEZ, E. **Microdosage des acides α -aminés et de peptides simples par l'intermédiaire de leurs sels complexes de cuivre. [Micro-estimation of α -amino-acids and simple peptides as their copper complexes.]** *Helv. chim. Acta*, 1955, **38**, 841-847. [*Lab. Org. Pharm. Chem., Univ. Geneva.*] English summary.

Dowex-50 containing cupric and phosphate ions was used as a specific cupric ion donor. Cu in soluble form was estimated iodimetrically. The minimum amounts of α -amino-N which can be measured are 0.2 μ g. per ml. for oligopeptides and 0.01 μ g. per ml. for amino-acids.—H. G. Gray.

4570

BODE, F. **Eine Vereinfachung und Verbesserung der Methode zur quantitativen Bestimmung von Aminosäuren und Peptiden mittels des Ninhydrin-Kupferkomplexes. [Simplification and improvement of the method of quantitative estimation of amino-acids and peptides by means of the ninhydrin-copper complex.]** *Biochem. Ztschr.*, 1955, **326**, 433-435. [*Lab. Klin. Chem., Frankfurt a. M.*]

The method previously described (Abst. 1216, Vol. 23) is improved by dipping the paper in a solution of ninhydrin in acetone, as suggested by Smith (Abst. 2644, Vol. 23), instead of spraying it. As little as 0.5 μ g. amino-acid N can be estimated. The method can be used also to estimate the total free amino-N in biological fluids.—W. M. Deans.

4571

HARDY, T. L., HOLLAND, D. O. and NAYLER, J. H. C. **One-phase solvent mixtures for the separation of amino acids.** *Anal. Chem.*, 1955, **27**, 971-974. [*Med. Chem. Div., Beecham Research Laboratories, Ltd., Botolph Claydon, Surrey.*]

Of 18 amino-acids 16 can be identified on a single one-dimensional chromatogram or all 18 on 4 separate one-dimensional chromatograms. Treatment of developed chromatograms with cyclohexamine or dicyclohexamine before spraying with ninhydrin gives variations in the colours produced and helps identification. The compositions of 17 useful solvent mixtures are given.

H. G. Gray.

ORESKIES, I. and SAIFER, A. **Qualitative determination of amino acids in protein hydrolyzates by circular paper chromatography.** *Anal. Chem.*, 1955, **27**, 854-856. [*Dept. Phys. Chem., Div. Labs., Jewish Chronic Dis. Hosp., Brooklyn 3, N.Y.*]

Two circular paper chromatograms were developed separately with phenol and a mixture of butanol and acetic acid as the solvents. Half of each chromatogram was stained with isatin and the other half with ninhydrin. From the separate bands and different colours produced a hydrolysate of human serum was thus qualitatively analysed for the constituent amino-acids.—A. Hepburn.

4573

RAO, N. A. N. and WADHWANI, T. K. **Quantitative estimation of amino-acids by circular paper chromatography.** *J. Indian Inst. Sci.* [A], 1955, **37**, 130-140. [*Sec. Pharmacol., Indian Inst. Sci., Bangalore 3.*]

The solvents used were *n*-butanol saturated with water, and butanol : water : acetic acid (40 : 5 : 5 and 40 : 5 : 15).—H. G. Gray.

4574

GRASSMANN, W., HANNIG, K. and PLÖCKL, M. **Eine Methode zur quantitativen Bestimmung der Aminosäurezusammensetzung von Eiweißhydrolysaten durch Kombination von Elektrophorese und Chromatographie. [A method for the quantitative estimation of the amino-acid constituents of protein hydrolysates by combined electrophoresis and chromatography.]** *Hoppe-Seyler's Ztschr.*, 1955, **299**, 258-276. [*Max-Planck-Inst. Eiweiß Lederforsch., Regensburg.*] English summary.

The protein hydrolysate is first separated by continuous electrophoresis at pH 3.9 into 4 fractions, basic amino-acids, neutral amino-acids, glutamic acid and aspartic acid, sometimes with cysteine acid as a fifth. The neutral fraction is then

separated by electrophoresis at pH 2.3 to allow quantitative separation of glycine and alanine from the rest. Further separation of basic and neutral amino-acids is achieved by one-dimensional paper chromatography. After development of the spots with ninhydrin quantitative estimation is made by photometry in monochromatic light of wavelength 550 m μ ., the paper first being rendered transparent with Transparenzöl.

The mean error with standard mixtures was about 3 per cent. The method was used for hydrolysates of casein, collagen, procollagen and insulin.

D. Duncan.

4575

RIDER, A. A. and McCOLLUM, E. V. The extraction of amino acid-containing substances from urine. *J. Lab. Clin. Med.*, 1955, **45**, 215-218. [Johns Hopkins Univ., Baltimore, Md.]

Amino-acids from urine, free or combined, were separated into simpler fractions by precipitation brought about by neutralisation with ammonia of extracts of urine solids in a solution of camphor-sulphonic acid and acetone. Hippuric acid was the only material containing amino-acids which was not precipitated. Undissolved material could be extracted after acid hydrolysis. Trichloro-acetic and benzenesulphonic acids were not found suitable.—A. Hepburn.

4576

HACKMAN, R. H. and LAZARUS, M. Paper chromatography of mixtures of amino acids containing glutamic or aspartic acid. *Biochim. biophys. Acta*, 1955, **17**, 147-148. [Div. Entomol., C.S.I.R.O., Canberra.]

The anomalous results obtained by Beck and Ebrey (Abst. 1612, Vol. 25), in which paper chromatography of mixtures of glycine and glutamic acid gave rise to 3 spots, were examined. It was concluded that there is no reaction between the acids and it is suggested that the results are due to the high amino-acid concentrations used. Under these conditions there may be interaction between glutamic acid and phenol of the developing solvent and, in addition, different ionic species of this amino-acid may give rise to multiple spots.

H. G. Bray.

4577

PFLIEDERER, G., GRUBER, W. and WIELAND, T. Eine enzymatische Bestimmung der L-Asparaginsäure. [Enzymic estimation of L-aspartic acid.] *Biochem. Ztschr.*, 1955, **326**, 446-450. [Inst. Org. Chem., Univ. Frankfurt a. M.]

A method for estimating L-aspartic acid, from 10 to 120 μ g. in 0.1 ml., claimed to be rapid, accurate and highly specific, depends on enzymic transamination to oxaloacetic acid. This is reduced with maleic acid dehydrase and dihydrodiphosphopyridine nucleotide, which is estimated spectro-

photometrically at 366 m μ . Results for insulin, horse haemoglobin and bovine serum albumin are in good agreement with those in the literature.

W. M. Deans.

4578

ZAMIR, A. and LICHTENSTEIN, N. A colorimetric method for the estimation of glutamic acid in protein hydrolysates. *Anal. chim. Acta*, 1955, **12**, 577-579. [Dept. Biol. Colloidal Chem., Hebrew Univ., Jerusalem.] French and German summaries.

The hydrolysate is autoclaved at 125° C. and pH 3 to 4 for 4 hr. to convert glutamic acid to pyrrolidone carboxylic acid. This is estimated by means of a colour reaction with hydroxylamine and ferric chloride.—H. G. Bray.

4579

WEISS, S., ANDERSON, E. I., HSU, P. T. and STEKOL, J. A. An adaptation of the Floyd-Lavine procedure for the isolation of methionine to tracer work. *J. Biol. Chem.*, 1955, **214**, 239-244. [Lankenau Hosp. Res. Inst., Philadelphia, Pa.]

The procedure of Floyd and Lavine (*J. Biol. Chem.*, 1954, **207**, 119) for isolating methionine from protein digests as the methyl sulphonium bromide was modified to ensure separation from cystine, cysteine, cystathionine and homocystine, though not homocysteine. The product was shown to be chromatographically pure. No exchange was found between the methyl groups of methionine and the methanol used in the procedure.

4596

BIRK, Y. and BONDI, A. Separation and determination of acetic and lactic acids by paper partition chromatography and its application to silages. *Analyst*, 1955, **80**, 454-457. [Animal Nutrit. Lab., Agric. Res. Stat., Rehovot, Israel.]

Ammonium salts of the acids are transferred to 2 papers. One of these is chromatographed immediately, with *n*-butanol saturated with an equal

volume of 1.5 *N* redistilled ammonia as solvent. Acetic and lactic acids run together and their sum is estimated by measuring the spot area after spraying with a mixture of methyl red, bromothymol blue, formol and ethanol (pH 5.2). The other paper is left at room temperature for several hours to allow volatilisation of the salts of volatile acids. Chromatography then enables lactic acid to be estimated alone.—H. G. Bray.

4597

PFELEDERER, G. and DOSE, K. Eine enzymatische Bestimmung der L(+)-Milchsäure mit Milchsäuredehydrase. [Enzymic estimation of L(+)-lactic acid with lactic acid dehydrase.] *Biochem. Ztschr.*, 1955, **326**, 436-441. [Inst. Org. Chem., Univ. Frankfurt a. M.]

In presence of lactic acid dehydrase from rabbit muscle in carbonate-bicarbonate buffer at pH 9.7, lactic acid reacts with diphosphopyridine nucleotide to form pyruvic acid and dihydrodiphosphopyridine nucleotide; the latter is estimated by the Beckman spectrophotometer and the lactic acid values are read from a standard curve. The method and its application to human blood and mouse muscle and liver are fully described. Amounts from 3 to 35 μ g. L(+)-lactic acid can be estimated; with concentrations from 1 to 10 μ g. per ml. in blood the mean error is from 3.5 to 4 per cent.—W. M. Deans.

4598

REIFER, I. Nowa metoda mikrooznaczania kwasu cytrynowego. [A new method for the micro-estimation of citric acid.] *Acta biochim. polon.*, 1955, **1**, 293-305. [Inst. Biochem. SGGW, Warsaw.] English and Russian summaries.

The method is based on the pentabromoacetone reaction in presence of chloroform, which permits separation from permanganate and H_2O_2 , the presence of which in excess causes interference. The rose-red colour appearing when pentabromoacetone reacts with resorcinol is used for the colorimetric estimation of citric acid. (From summary.)

KROL, B. M. and DEN HERDER, P. C. A routine method for the determination of copper in milk and in dried milk. *Nederlands Melk Zuivelijdschr.*, 1955, 9, 56-62. [Govt. Dairy Stat., Leyden.] Dutch summary.

Milk or reconstituted milk was extracted with alcoholic HCl, the milk protein being precipitated at the same time. Citric acid was added to the clear filtrate to prevent turbidity with phosphate, the solution was made alkaline with ammonia and diluted with ethanol and Cu was estimated in a

N.A. and R., October 1955

photo-electric colorimeter after reaction with sodium diethyldithiocarbamate. From duplicate estimations the standard deviations of individual samples were calculated to be 19 $\mu\text{g. Cu}$ per kg. milk and per 100 g. dried milk, respectively. The mean of the results of this method for 72 samples of milk was 8 $\mu\text{g. Cu}$ per kg. milk higher than the mean obtained by an incineration method.

MURACA, R. F. and BONSACK, J. P. Photometric determination of sodium in blood serum with violuric acid. *Chemist-Analyst*, 1955, 44, 38-42. [Lehigh Univ., Bethlehem, Pa.]

Ashed serum was suspended in water and SO_4^{2-} , PO_4^{3-} , CO_3^{2-} and Cl^- were removed by precipitation with Ba and Ag acetates. The resulting acetates were dissolved in a solution of violuric acid in anhydrous dimethylformamide saturated with K violurate and the optical density of the resulting Na violurate was measured by spectrophotometer. By reference to standard curves obtained from solutions containing NaCl and a synthetic serum-mineral mixture the Na content of serum was estimated. Results compared favourably with those of the flame photometer method and accuracy was consistently within 4 m. equiv. per litre.—A. Hepburn.

SCHARRER, K. and JUNG, J. Zur Bestimmung des Gesamt-, Protein- und Sulfat-Schwefels in pflanzlichen Futtermitteln. [Estimation of total, protein and sulphate sulphur in plant feedingstuffs.] *Ztschr. Tierernährung Futtermittelk.*, 1955, 10, 25-31. [Agric. Chem. Inst., Justus Liebig Hochschule, Univ. Giessen.]

For total S the plant material was mixed with MgO and ashed with concentrated and then with

fuming HNO_3 on a sandbath. The neutral S was oxidised to sulphate for gravimetric estimation.

For extraction of sulphate S the plant material was heated with 5 per cent. HCl and the solution was clarified with activated charcoal or phosphotungstic acid, which gave results in good agreement.

For protein S precipitation with phosphotungstic acid was used; the protein precipitate was ashed and the S was estimated gravimetrically as sulphate.

The methods were used on lucerne hay, meadow grass and young sunflowers. With increase in total S, both sulphate and neutral S rose, especially the former.—D. Duncan.

EDWARDS, S. J. and HASKINS, M. D. The determination of antibiotic content in supplemented feeding-stuff. *J. Sci. Food Agric.*, 1955, 6, 218-223. [Agric. Res. Council, Field Stat., Compton, near Newbury, Berks.]

Aureomycin and penicillin were estimated in meals by 2 methods.

In the serial-dilution method the concentration of an aqueous extract of the meal was estimated by the capacity of falling dilutions to inhibit the growth of

a sensitive strain of *Streptococcus agalactiae* compared with extracts of standard control meals. Non-specific substances in the meal did not interfere with the accuracy.

In the paper-disc method a little of a volatile solvent extract of meal was absorbed on to a filter-paper disc, dried and placed on an agar medium inoculated with *Bacillus cereus*. The concentration of the unknowns was calculated from the average diameters of the inhibiting zones by reference to a control graph. The method was satisfactory but more difficult.—A. Hepburn.

CLINICAL AND EXPERIMENTAL

4638

ZIFF, R. E., WEBBER, J. M. and GROVE, G. R. A gravimetric technique for the determination of plasma volumes with radiiodinated human serum albumin. A comparison of routine plasma volume determination methods using radiiodinated human serum albumin and Evans blue dye. *J. Lab. Clin. Med.*, 1955, 45, 648-652; 800-805. [Dept. Res., Miami Valley Hosp., Dayton, Ohio.]

Human serum albumin labelled with radio-active iodine ($20 \mu\text{C}$) is injected into one arm. A sample is withdrawn from the other and weighed, the sp. gr. is estimated in part by the copper sulphate method and the radio-activity is measured by a scintillation counter. The remainder of the sample is centrifuged and the plasma treated as was the whole blood.

The gravimetric radio-active iodine method was found to be more precise and to have fewer technical and clinical limitations than the Evans Blue method.—H. G. Bray.

4639

SCHWARTZKOPFF, W. and BARTELHEIMER, H. Fraktionierte Gewebssaftuntersuchung. 8. Zum Übertritt des Farbstoffes Evans Blau (T 1824) von der Blutbahn in den extravasalen Raum. [Studies of fractionated tissue juice. 8. On the passage of the dye Evans Blue (T 1824) from the bloodstream into the extravascular space.] *Ztschr. ges. exp. Med.*, 1954-55, 125, 409-418. [I. Med. Klin., Städt. Krankenhaus Moabit, Berlin.]

The presence of Evans Blue in tissue fluid could be demonstrated about 20 min. after injection and equilibrium was reached in about 8 hr. The concentration of dye in tissue fluid was always lower than that in serum and it is suggested that it depends on the concentration and transfer of albumin. It is calculated that the extravascular space is equivalent to from 9 to 11 per cent. of the bodyweight.—H. G. Bray.

4640

STOLL, G. and BREITENSTEIN, C. L'instabilité des densités optiques du sérum sanguin coloré. Cause d'erreur dans la détermination du volume plasmatique par la méthode du bleu de Geigy. [Instability of the optical density of dyed blood serum. A cause of error in the estimation of plasma volume by the Evans Blue method.] *Presse méd.*, 1955, 63, 497. [Clin. Chirurg. A, Centre Recherches Chirurg., Strasbourg.]

It is suggested that the effect of time on the optical density of dyed blood serum is due to oxidation-reduction changes in the dye and to flocculation produced by changes in pH. It is recommended that readings be taken as soon as possible.—H. G. Bray.

4641

BOWERS, D., SHEPHERD, J. T. and WOOD, E. H. A constant-rate indicator-infusion technic for the measurement of central vascular volume in man. *Canad. J. Biochem. Physiol.*, 1955, 33, 340-348. [Sect. Physiol., Mayo Clin., Rochester, Minn.]

Evans Blue was injected into the right ventricle or pulmonary artery and arterial dilution patterns were recorded by means of a cuvette oximeter connected to an indwelling needle in the radial artery. From these patterns the amount and concentration of dye in the intravascular space between the sites of injection and sampling were estimated and the "central vascular volume" was calculated from a formula, the derivation of which is discussed. The values obtained are compared with others in the literature.—H. G. Bray.

4642

FALLER, I. L., PETTY, D., LAST, J. H., PASCALE, L. R. and BOND, E. E. A comparison of the deuterium oxide and antipyrine dilution methods for measuring total body water in normal and hypodryc human subjects.

FALLER, I. L., BOND, E. E., PETTY, D. and PASCALE, L. R. The use of urinary deuterium oxide concentrations in a simple method for measuring total body water. *J. Lab. Clin. Med.*, 1955, 45, 748-758; 759-764. [Dept. Biochem., Northwestern Univ. Med. Sch., Chicago, Ill.]

D₂O spaces were consistently found to be significantly larger than antipyrine spaces. For the estimation of total body water D₂O can be injected or given by mouth and is more suitable for oedematous subjects, since it equilibrates rapidly where antipyrine may fail to do so within 24 hr.

An accurate method for the estimation of D₂O in urine is described. Identical values for the body water of 13 normal male subjects were obtained by the serum and urine methods. A negligible amount of D₂O is lost in urine during equilibrium.—H. G. Bray.

4643

FRIS-HANSEN, B. The measurement of total body water and extracellular fluid in children. Changes in body water compartments during

growth. *Helv. paediat. Acta*, 1955, 10, 7-11; 12-16. [Dronning Louises Child. Hosp., Copenhagen.]

4644

REILLY, W. A., SCOTT, K. G., WINTERS, R. W. and HELWIG, H. L. Anionic resin measurement of protein-bound I^{131} in euthyroid children. *Amer. J. Dis. Child.*, 1955, 89, 572-574. [Dept. Paediat., Sch. Med., Univ. California.]

The rate of thyroid hormone production was estimated in 14 euthyroid children by giving them ^{131}I by mouth, separating inorganic and organic I in the plasma by adsorption of the former on anionic resin and measuring the activity of both fractions (see *Abst. 1651*, Vol. 25). The children appeared to release protein-bound I earlier and in greater amounts than 27 adults (loc. cit.).

A. Hepburn.

4645

INGBAR, S. H. Simultaneous measurement of the iodide-concentrating and protein-binding capacities of the normal and hyperfunctioning human thyroid gland. *J. Clin. Endocrinol.*, 1955, 15, 238-264. [Dept. Biophys., Army Med. Serv. Grad. Sch., Walter Reed Army Med. Centre, Washington 12, D.C.]

A tracer dose of 50 μC . of carrier-free inorganic ^{131}I was injected intravenously into each patient. Measurements of radio-activity were made over the neck and thigh for the next 2½ hr. and 4 blood samples were drawn from 40 to 60 min. after administration of the ^{131}I and radio-activity was measured in 0.5 ml. serum. From the data obtained a method of estimating the simultaneous concentration of inorganic iodide in the thyroid and the binding of the iodide to protein is described.

A study was made with 28 normal subjects and 20 patients with Graves' disease. In the second group there was an increased rate of iodide binding to protein and also an increase in the iodide-concentrating capacity of the gland. The importance of each of these functions in the production of thyroid disease is stressed.—B. W. Simpson.

4646

MORELAND, F. B. and GURGILOLO, A. E. The use of the urinary pigment: creatinine ratio as a measure of basal metabolic rate and thyroid activity. *J. Lab. Clin. Med.*, 1955, 45, 352-356. [Dept. Biochem., Baylor Univ. Coll. Med., Houston, Tex.]

The basal metabolic rate derived from the calculation of the ratio of urinary pigment to creatinine (P/C) was compared with the B.M.R. calculated from oxygen consumption, with clinical status and with radio-iodine uptake. On 22 adult males

46 estimations of P/C ratios were made on the same morning as the measurement of B.M.R. by oxygen consumption. The coefficient of correlation obtained was only 0.36. The 2 tests agreed in 61 per cent. of the observations. The P/C B.M.R. corresponded with clinical status in 62 per cent. of all the observations and in 71 per cent. of those made on euthyroid and hyperthyroid patients. The B.M.R. calculated by oxygen consumption corresponded with clinical status in 81 per cent. of the observations. The P/C B.M.R. corresponded with iodine uptake in 8 of 15 patients.

It is suggested that the estimation of P/C B.M.R., though not so reliable as estimation by oxygen consumption, may be of value when it is impossible to obtain an accurate measurement of oxygen consumption in the basal state. The method of estimating urinary pigment is given in detail.

B. W. Simpson.

4647

SCHOFFA, G. Die methodischen Fehlerquellen der Grundumsatzbestimmung. [Sources of error in methods for estimating basal metabolism.] *Ztschr. ges. inn. Med.*, 1955, 10, 45-46. [Deutsch. Akad. Wissensch., Inst. Med. Biol.]

The relative effect on the end result is discussed of errors in the measurements that have to be made in estimating basal metabolism. It is concluded that only errors in estimating the volume of expired air and the concentration of O_2 are important, and that they do not result from shortcomings in the apparatus. To achieve accuracy the measurements should be repeated again and again until consistent results are obtained.

4649

LORFFLER, R. K., RAPPOPORT, D. A. and COLLINS, V. P. Radioiron citrate as tracer to determine disappearance rate of plasma iron in normal subjects. *Proc. Soc. Exp. Biol. Med.*, 1955, 88, 441-444. [Dept. Radiol., Baylor Univ., Texas Med. Centre, Houston.]

In 6 patients, none with disease affecting the haemopoietic system, 2 disappearance rates of Fe

were measured on the same day, during the forenoon after an injection of radio-active ferric citrate and during the afternoon after an injection of a sample of the patient's own plasma which had been incubated with radio-active ferric citrate. The rates of disappearance from the 2 forms were similar. The use of radio-active Fe as citrate is suggested for simplifying the administration of a tracer in clinical studies of Fe turnover.

KLAKEG, C. H., PRUITT, R. D. and BURCHELL, H. B. A study of electrocardiograms recorded during exercise tests on subjects in the fasting state and after the ingestion of a heavy meal. *Amer. Heart J.*, 1955, 49, 614-625. [Mayo Clin., Rochester, Minn.] Interlingua summary.

The subjects were 64 men and 12 women aged from 19 to 62 years, but mostly between 40 and 59, most of whom had complained of pain in the chest. Partly on the results of the test, 26 of the men and 7 of the women were diagnosed as having coronary disease. The electrocardiograms were recorded before and after exercise consisting of 40 ascents and descents of two 9-in. steps, or less if the subject complained. The test was made at least 2 hr. after food and repeated on the same day within an hour after what the subject considered a large meal.

The average heart rates in the fasting test were 78.6 at rest, 101.2 immediately after exercise and 82.6 after a 5-min. rest. After a meal the corresponding rates were 86.4, 112.6 and 91.3. QT intervals were within the normal range, but the average height of T waves in lead V_5 was less after the meal than fasting in all subjects, and in fasting tests less after exercise than before in the subjects thought to have heart disease. The level of the RS—T segments relative to the P—R segments in lead V_5 was lower after a meal in all subjects, and there was no diagnostic advantage in performing the test after a meal.—D. Duncan.

4653

SCARU, A. and SCHIANO, S. Tentativo di applicazione della reazione di Nagler alla diagnostica sierologica della malattia aterosclerotica umana. [Application of Nagler's reaction to the serological diagnosis of atherosclerosis in man.] *Acta gerontol.*, 1954, 4, 179-187. [Ist. Patol. Spec. Med., Univ. Naples.] English and French summaries.

Nagler's reaction as used by Horlick (Abst. 617, Vol. 25) was modified in that the lecithinase activity of *Cl. welchii* toxin was replaced by that of a phenol solution.

A constant and significant difference in final turbidity values was found between 10 normal and 20 atherosclerotic subjects, related to the increase of the β : α lipoprotein ratio in the latter. In other subjects with essential hypertension, hyperlipaemia and other disorders the results were less constant. The method is considered promising for clinical diagnosis of atherosclerosis.—D. Duncan.

QUICK, A. J. Die Ein-Stufen-Methode der Prothrombinzeit-Bestimmung. [The one-stage method of estimating prothrombin time.] *Deutsch. med. Wochenschr.*, 1955, 80, 620-621. [Dept. Biochem., Sch. Med., Marquette Univ., Milwaukee, Wis.]

In the presence of excess Ca and a source of thromboplastin the formation of thrombin is proportional to the concentration of prothrombin, a labile substance (Abst. 2959, Vol. 13) and a stable substance in the plasma. For a one-stage method of estimating prothrombin time it is essential to use as source of thromboplastin rabbit brain treated with acetone, since this is free of both the labile and the stable substance. Normal human plasma has then a constant prothrombin time of 12 sec. Both accessory substances must be present, but in excess they do not reduce the time, which is therefore determined primarily by the prothrombin itself.

Adult plasma contains a prothrombin precursor, prothrombinogen, which is absent from the blood of newborn infants. The two-stage prothrombin method did not distinguish free prothrombin from the precursor, but the one-stage method does not estimate prothrombinogen. The prothrombin time of newborn infants is therefore the same as that of adults.

The prothrombin time is normal in haemophilia, thrombocytopenia and von Willebrand's disease, and the method can be used for distinguishing these disorders from disorders in which prothrombin is low. Increased prothrombin time of congenital origin is usually due to deficiency of only one substance, but acquired hypoprothrombinaemia usually involves more than one, and diagnosis is more complex.—D. Duncan.

SMITH, A. M. and REID, J. T. *Use of chromic oxide as an indicator of fecal output for the purpose of determining the intake of pasture herbage by grazing cows. J. Dairy Sci., 1955, 38, 515-524. [Dept. Animal Husb., Cornell Univ., Ithaca, N.Y.]*

Five trials with 17 individual cows were made to investigate the use of chromic oxide for the estimation of total faeces voided by cows during

pasture herbage trials. From 10 to 28 g. Cr_2O_3 was given once or twice daily, in capsules or mixed with a small amount of concentrate feed. The daily pattern of Cr_2O_3 excretion was studied, and it was found that least Cr_2O_3 was recovered at 2 p.m., and most at midnight. Samples taken at 6 a.m. and 4 p.m. for 7 consecutive days could be used for accurate estimation of the total faeces voided, as found by the use of collection bags. The method of giving the Cr_2O_3 did not affect the accuracy.—T. D. Bell.

4659

JAAP, R. G. *Sampling body weight of growing chickens. Poultry Sci., 1955, 34, 396-397. [Ohio State Univ., Columbus 10.]*

Samples of 75 chicks, taken from groups containing from 200 to 1500 birds at 8 weeks of age, were weighed and the means were found to differ from the true means for the corresponding whole groups (1.0 to 3.4 lb.) by not more than 0.08 lb. in a series of 12 tests and showed no tendency for a systematic bias. The samples were obtained by grouping 60 to 100 chicks against a wall with a catching frame and allowing all but 25 to escape at the sides; these were weighed and 2 further samples were taken at different points in the pen.—K. J. Carpenter.

4660

M McNALLY, E. H. *Calculation of the moisture and protein content of market chickens from the fat content. Poultry Sci., 1955, 34, 152-155. [U.S. Dept. Agric., Agric. Res. Serv., Animal and Poultry Husb. Res. Branch, Beltsville, Md.]*

Regression equations for the relation of fat content to moisture, protein and ash contents in fattened and unfattened hens and cockerels are presented. It was found that growth, fattening and sex did not affect the relationships. The calculations from fat content of protein, moisture and ash of breast muscle and ash of total edible meat and leg muscle were only fairly accurate, but the accuracy of the other calculations was high.

LUCKEY, T. D., WAGNER, M., REYNIEERS, J. A. and FOSTER, F. L. (Jr.) Nutritional adequacy of a semi-synthetic diet sterilized by steam or by cathode rays. *Food Res.*, 1955, 20, 180-185. [Lobund Inst. Res. Life Sci., Univ. Notre Dame, Ind.]

Three generations of Swiss mice were reared in small numbers (16 first generation dams) on a semi-synthetic diet of casein (Labco) 25, maize starch 54, cellophane 2, maize oil 6.8, minerals 6, yeast and liver extracts 5 per cent., with liberal amounts of vitamins (details supplied), given to appetite, or the same sterilised by steam or by cathode rays under specified conditions, along with non-sterile tap water.

General appearance, growth, reproduction and lactation were similar in the 3 groups of mice and it is considered that sterilisation by cathode rays does not have any toxic effect. Analyses showed that neither process destroyed much of the vita-

mins, except vitamin B₁, of which less than a third remained, but it is emphasised that in any case the amounts were ample. Cathode rays destroyed rather less than steam did.

VENKATAPPAIAH, D. and BASU, K. P. Non-protein nitrogenous constituents of milk. 3. Effect of different heat treatments. *Indian J. Dairy Sci.*, 1955, 8, 1-8. [Indian Dairy Res. Inst., Bangalore.]

The methods of estimation were as in part 1 (Abst. 183, Vol. 23). Pasteurisation of cow or buffalo milk by the holder or the high-temperature, short-time method in the laboratory, or by the second method in the dairy, did not affect total N, total N.P.N. or N.P.N. constituents. When milk was brought just to the boil (at altitude 3000 ft.) and cooled, with shaking to prevent a skin forming, urea N and uric acid N decreased and ammonia N increased, but not significantly. When the milk was boiled for 30 min. and then cooled, these changes reached significance. In the last 2 processes a small amount of creatine was transformed into creatinine.—W. M. Deans.

TAMSA, A. F. A study of the volatile fraction isolated from oxidized milk fat. 1. Isolation, preliminary characterization, and chromatographic separation of the volatile fraction. 2. Further characterization of compounds responsible for the oxidized flavor. *J. Dairy Sci.*, 1955, 38, 284-291; 478-498. [Dairy Indust. Sect., Iowa Agric. Exp. Stat., Ames.]

1. Milk fat was oxidised by exposure to the atmosphere at different temperatures and deodorised by steam distillation. Only the distillate possessed an oxidised flavour, which could be removed by extraction with Skellysolve B and was

N.A. and R., October 1955

apparently due to carbonyl compounds, as peroxides and epoxides were absent. The carbonyl compounds were not all recovered in the distillate and the amount obtained was much less after oxidation for 1 month at 40° or 25° C. than after oxidation for 24 hr. at 100° C.

The fraction extracted with Skellysolve B had characteristic ultraviolet absorption maxima at about 215 and 260 $m\mu$, indicating conjugated monoene and diene carbonyl compounds, respectively. Changes in absorption were distinct before other signs of oxidation appeared. The diene compounds were less stable than the monoenes when this fraction was stored. On the basis of the ultraviolet absorption of the eluate the fraction was separated by chromatography. The oxidised flavour was present in the first fractions, in those with an absorbance at 215 $m\mu$ and in the eluate just preceding them.

Compounds with no appreciable absorption in the ultraviolet region apparently also contributed to the oxidised flavour.

2. The volatile fraction from milk fat oxidised at 100° C. and soluble in Skellysolve contained 3 carbonyl compounds, unconjugated unsaturated, apparently responsible for the oxidised flavour, conjugated monoene and a little conjugated diene. These compounds were probably ketonic, the first 2 possibly tautomeric, and the last one was unstable. A promising method for their separation depended on chromatography on Celite, the reaction of the eluate fractions with semi-carbazide and the recrystallisation of the semi-carbazones.

TOLLENAAR, F. D. Vetbederf in melkpoeder. [Rancidity of fat in dried milk.] *Voeding*, 1955, 16, 195-204. [Centraal Inst. Voedingsonderzoek T.N.O., Utrecht.] English summary.

The production of dried milk is of great importance in the Netherlands. Of the total of 4.9 million tons of milk produced in 1954 about 11 per cent. was dried. Whole milk and whole milk with added fat, up to 42 per cent., and skimmed milk are dried. The effects of pre-heating and of roller and spray drying are discussed. Spray-dried whole milk has a higher percentage of "tallowy" and roller-dried of "stale" samples.

The chemical changes leading to rancidity and flavour defects, the defects of processing that accelerate these changes and what can be done to avoid them are discussed.—I. Leitch.

VAN KREVELD, A. and VAN MINNEN, G. Calcium and magnesium ion activity in raw milk and processed milk. *Nederlands Melk Zuivelijdschr.*, 1955, 9, 1-29. ["Friesland" Co-operative Condensery, Leeuwarden.] Dutch summary.

The Ca and Mg ion activity of fresh and treated milks was measured by shaking samples of them with a quantity of the cation-exchange resin Duolite C 20 which had been conditioned by treatment with chlorides of Na, K, Ca and Mg. The load which was least affected by the process provided a measure of the cation activities in the milk. If K ions in raw milk were assumed to be free than Na ions were found also to be free, but of Ca and Mg only part, about one-fourteenth and one-sixth, respectively, was present as free ions. Data are given also for changes produced by pasteurisation, when both Ca and Mg ion activities were significantly reduced, and by condensation and sterilisation, when in the one case that of Ca and in the other that of Mg was diminished most.

GRISWOLD, R. M. The effect of different methods of cooking beef round of Commercial and Prime grades. 1. Palatability and shear values. 2. Collagen, fat and nitrogen content. *Food Res.*, 1955, 20, 160-170; 171-179. [Univ. Chicago, Ill.]

1. Meat from paired rounds from Hereford steer carcasses, 4 of U.S. Commercial and 2 of Prime grade, was cooked by a standard braising method to 185° F. (85° C.) or by 14 other methods, namely, braising to 176° or 199°, or to 185° with previous scoring or pounding or treatment with 2 papain preparations or vinegar, or to 185° with vinegar or without water, or pressure cooking to 185° at a pressure of 5, 10 or 15 lb. per sq. in., or roasting to 185° in an oven at 250° or 300°. It was judged by a panel for aroma, flavour of fat and of lean, tenderness, juiciness and acceptability, and shear values were measured. The results are tabulated and analysed statistically.

Most variants of the standard braising method did not improve quality, except that tenderness was increased by pounding or by treatment with

papain, but not by scoring or soaking in vinegar, and the last impaired the flavour. Braising gave rather better results than pressure cooking. Roasting at 250° F. took a long time and the outside appearance of the meat was unsatisfactory, but flavour and tenderness were excellent. Beef from Prime grade carcasses generally, but not always, surpassed that from Commercial grade carcasses in flavour and tenderness. On the whole, the different cooking methods affected both grades in the same way.

2. In the meat cooked as described above pH was measured and moisture, fat by acid hydrolysis, total N by the Kjeldahl method, free amino-N by formal titration, and collagen by the method of Lowry *et al.* (Title 817, Vol. 11), and the fat content of the drippings, were estimated. The results are tabulated and analysed statistically.

The results suggested that the total amount of free amino-N does not increase during cooking and that the more soluble nitrogenous constituents go into the drippings. The average loss of collagen for all cooking methods was 61 per cent. Loss of collagen tended to increase with the internal temperature of the meat and was high in meat roasted at 250° F. or soaked in vinegar and low in meat braised without water; pounding, scoring or treatment with papain had little effect. Cooked beef from Commercial grade carcasses contained more collagen than that from Prime grade carcasses.

TADLE, J., LEWIS, M. N., WINTER, A. R. and JAAP, R. G. Cooked, edible meat in parts of chicken. 1. Broilers. *J. Amer. Dietetic Assoc.*, 1955, 31, 597-600. [Dept. Dietetics, Ohio State Univ., Columbus.]

This study was based on 10 male and 10 female 10-week-old broilers of each of 3 crosses, of average liveweight 3.4 lb. After losses in dressing and evisceration had been found, the carcasses were cut into parts (illustrated), wrapped in aluminium foil and cooked at 15 lb. pressure for 20 min.

The results include the following: dressing loss, males 10.9, females 12 per cent.; evisceration loss as percentage of liveweight 26, 24.4; overall cooking loss 23.0, 25.8 per cent. Wings lost 16.1, legs and thighs 23.9, breast 24.0, back 24.0 per cent.; giblets lost more. Cooked edible meat amounted to 37.5 per cent. of liveweight; differences between sexes and crosses were not significant. For the parts the percentage yields of cooked edible meat were: heart 67.2, liver 66.8, breast 63.4, gizzard 58.6, legs and thighs 53.3, wings 50.0, back 41.7.—W. M. Deans.

4678

SZCZYGIŁŁE, A. and SICZKÓWNA, J. Badania nad wzbogacaniem pieczywa z różnych gatunków

małki. [Experiments on bread enrichment.] *Roczn. Państwowego Zakł. Hig.*, 1955, 6, 55-74. Russian and English summaries.

The object was to find a recipe for an enriched bread, consumption of which in amounts of 500 to 750 g. daily would cover nutritional requirements for short periods, except for vitamins A, D and C. The basal ingredients of the dough were 100 g. wheat or rye flour of different extractions, margarine 10, sugar 5 and skimmed milk powder 6 g. and the additions tested were yeast 2 to 10 per cent., beans 10 per cent. or blood 20 to 60 per cent. by weight, and calcium carbonate. The biological value of the different breads was tested on rats.

The yeast-fermented breads had a high biological value but with more than 4 per cent. yeast had a bitter taste. Addition of beans to this bread did not improve the biological value. Bread made with added blood had poor organoleptic qualities. Leaven-fermented bread of 82 per cent. extraction rye flour had a better taste than yeast-fermented bread, but did not keep well. (From summary.)—J. S. Thomson.

JANSEN, A. P., VAN DER LINDEN, A. C. and WÖSTMANN, B. S. J. Die Wirkung der Ammoniumpersulfat-Behandlung von Mehl auf den Methioningehalt des Brotes. [The effect of ammonium persulphate treatment of flour on the methionine content of bread.]

SCHORMÜLLER, J. Die Wirkung der Ammoniumpersulfat-Behandlung von Mehl auf den Methioningehalt des Brotes. Erwiderung auf die gleichlautende Arbeit von A. P. Jansen, A. C. van der Linden und B. S. J. Wöstmann. [The effect of ammonium persulphate treatment of flour on the methionine content of bread. Reply to the paper with this title by A. P. Jansen, A. C. van der Linden and B. S. J. Wöstmann.] *Ztschr. Lebensmittel-Untersuch. Forsch.*, 1955, 100, 345-350; 350-351. [Nederlands Inst. Volksvoeding, Amsterdam; Inst. Lebensmittelchem., Techn. Univ. Berlin, Charlottenberg.]

Schormüller *et al.* (Abst. 2750, Vol. 23) reported a 20 per cent. loss of methionine from the gluten isolated from flours treated with ammonium persulphate. Jansen *et al.*, in experiments in which flour was treated and bread baked by ordinary practical methods, were unable to confirm this either chemically by the method of Baernstein (Title 2893, Vol. 6) used by Schormüller *et al.* or microbiologically with *Leuconostoc mesenteroides* P-60.

Schormüller retorts that the experiments were not comparable, and points out that he tested several flours of different extractions and took the crust into consideration, whereas they confined

N.A. and B., October 1955

themselves to the crumb of bread from a single flour. He reiterates a previous remark that the final decision must come from a biological experiment.—W. M. Deans.

NARAYANA RAO, M. and SWAMINATHAN, M. **The nutritive value of calcured rice.** *Bull. Central Food Technol. Res. Inst., Mysore*, 1954, **4**, 34. [Div. Biochem. Nutrit.]

Rice "calcured" by soaking in CaCl_2 solution and parboiling had a chemical composition similar, except for a much higher Ca content, to rice parboiled in tap water. The nutritive value was significantly improved.—A. Hepburn.

4681

SUBRAHMANYAN, V., RAMA RAO, G., MURTHY, H. B. N. and SWAMINATHAN, M. **Effect of storage on the chemical composition and nutritive value of groundnut flour, tapioca flour and their blends.** *Bull. Central Food Technol. Res. Inst., Mysore*, 1954, **4**, 31-33.

Tapioca flour, groundnut flour and a mixture of them in a 4:1 ratio were stored in gunny bags at room temperature and at 37° C. for 5 months. The free fatty acid and peroxide values of the groundnut flour and of the mixture increased during storage. Changes in tapioca flour were negligible. Increases were most in the mixture, which, however, did not become rancid like the groundnut flour. Between 12 to 25 per cent. of vitamin B_1 was lost from all samples. Temperature had no appreciable effect on any of these changes. The nutritive value of the flour mixture and the biological value of the groundnut protein [others were not tried] did not decrease on storage.—A. Hepburn.

4682

WALKER, G. W. **Removal of excess fluorine from drinking water for stock.** *East African Agric. J.*, 1955, **20**, 220. [Vet. Res. Lab., Mpwapwa, Tanganyika.]

Many of the natural waters in Tanganyika, both borehole and stream, contain over 18 p.p.m. F, an amount dangerous to livestock. By the application of calcium chloride to a bore-hole water containing 28 p.p.m. F this concentration was reduced to 13 p.p.m. The optimum amount of CaCl_2 was 0.54 g. per litre. The pH of the water was reduced from 8.8 to 7.4.—J. S. Thomson.

4683

ARNOLD, L. K. and JUHL, W. G. **The reduction of free gossypol in cottonseed flakes during solvent extraction.** *J. Amer. Oil Chem. Soc.*, 1955, **32**, 151-152. [Iowa Eng. Exp. Stat., Iowa State Coll., Ames.]

Vol. 25, No. 4

The free gossypol content of cottonseed flakes of initial moisture content 6.55 per cent. was reduced in a pilot plant by extraction with trichloroethylene at 122° F. The soluble protein content was higher than in meals in which the free gossypol content was reduced by heat treatment, but no feeding trial has been made.

MICHAEL, G. and BLUME, B. **Über das Verhalten einiger lebenswichtiger Aminosäuren beim biologischen Abbau in verschiedenen Pflanzen.** [The behaviour of some essential amino-acids in the biological decomposition of different plants.] *Arch. Tierernährung*, 1955, **5**, 41-51. [Inst. Agric. Chem., Friedrich-Schiller Univ., Jena.]

As a guide to losses in haymaking, laboratory studies were made on lucerne, red clover, summer barley and tobacco leaves, harvested before flowering and either dried at once at 65° C. or stored damp for 4 days in the dark. In the soluble fraction after coagulation of protein by heat, lysine and arginine were estimated by ascending chromatography on carboxyl paper with a sodium phosphate buffer at pH 8; arginine was also estimated colorimetrically, after electrophoretic separation, by the method of Sakaguchi, and tryptophan colorimetrically by xanthoprotein reaction.

Barley and lucerne stored damp lost 47 and 40 per cent. of their protein on a dry matter basis, clover only 16 per cent. Arginine and tryptophan in the soluble fraction increased about 3 times, lysine much less and the suggestion is made that it breaks up during storage. Combination of the results with those of Block and Bolling on the amino-acid composition of the plant proteins indicated losses from lucerne of 31 per cent. of its lysine, 13 per cent. of its arginine and 6 per cent. of its tryptophan. For barley the corresponding figures were 23, 25, 8 and for clover 12, 8, 6.

BARNETT, A. J. G. and BAXTER, J. *Laboratory studies on the initiation of the silage fermentation by means of whey.* *J. Brit. Grassland Soc.*, 1955, 10, 45-57. [Div. Agric. Biochem., Dept. Biol. Chem., Univ. Aberdeen.]

A small unreplicated trial did not show any effect of acid- or rennet-whey on pH or lactic acid production in fermenting grass slurries in glass aspirator jars, though volatile fatty acid production was apparently increased.—J. L. Corbett.

4689

ULVESLI, O., FYRILEIV, E. and BREIREM, K. En sammenligning av ensileringsmetoder for gras. [A comparison of ensiling methods.] *Norsk Landbruk*, 1954, No. 12, 262-264; No. 18, 390-391. English summary.

The quality of silage is important because of its effect on the quality of milk. Trials from 1946 to 1952 showed that the A.I.V. method was the most reliable for making grass silage of good quality. Under Norwegian conditions grass silage made without any addition was not a success, even when the grass was wilted, chopped or crushed. Chopping or crushing made it possible to use less A.I.V. acid. Sulphur dioxide led to practical difficulties and is not recommended. Small scale trials with Kofa salt were successful; it was not tried on a large scale. As a carbohydrate addition only steamed potatoes were tried, and no advantage resulted.—T. D. Bell.

4690

MURDOCH, J. C., BALCH, D. A., HOLDSWORTH, M. C. and WOOD, M. The effect of chopping, lacerating and wilting of herbage on the chemical composition of silage. *J. Brit. Grassland Soc.*, 1955, 10, 181-188. [Nat. Inst. Res. Dairying, Univ. Reading.]

In the trials reported the effects of chopping, lacerating, wilting and adding molasses to herbage for ensiling were investigated. Chopping and lacerating generally gave better silage, but even

when these methods were used silages high in butyric acid and volatile bases occasionally resulted. Excellent silage was made by adding molasses to chopped grass. The temperature was too high in silage made with wilted grass, but this could be controlled by chopping the wilted material, which was then more easily compacted.—T. D. Bell.

4691

AXELSSON, J. and KIVIMÄE, A. Effect of wilting and addition of kofasalt and molasses on ensiled clover. *Kgl. Lantbrukshögsk. Ann.*, 1954, 21, 41-48. [Inst. Animal Nutrit.]

Kofa salt (20 parts Ca formate and 3 parts Na nitrite) was added at 0.23 per cent. of the crop weight, molasses at 3 per cent. Effluent wastage, highest from molassed silage, was greatly reduced by wilting, which increased the average dry matter of the silage from 18 to 31.5 per cent. Both additives reduced dry matter losses and to a similar extent. Their effects on the chemical composition of the silage were slight.—J. L. Corbett.

4692

BRANDSMA, S. Verliezen bij het inkuilen van bietenkoppen en -blad. [Losses in ensiling beet tops and leaves.] *Landbouwoorlichting*, 1954, 11, 533-541. [Rijkslandbouwprefstat., Hoorn.]

Earlier results (*Landbouwoorlichting*, 1953, 10, 358-366) are compared with those of experiments in 1953-54 with chopped tops and leaves in an undrained and a drained silo and a pit, and with whole tops and leaves in a heap on the ground. The unchopped silage contained less acetic and lactic acids and more butyric acid and ammonia. Composition in terms of sand, sand-free dry matter, crude protein, crude fibre, other carbohydrates, ash, digestible true protein, starch equivalent and K, Na, Ca, Mg, P, Cl, SO₂ and Cu is given for each silo. Mean losses of proximate principles from silos were of the order of 30 per cent., and of crude fibre (cut, undrained) 6 and (cut, drained) 15 per cent.; from the pit, proximate principles about 40 and crude fibre 22 per cent.—I. Leitch.

4693

MURDOCH, J. C., BALCH, D. A., FOOT, A. S. and ROWLAND, S. J. The ensiling of lucerne with addition of formic and glycolic acids, molasses and barley meal, and with wilting. *J. Brit. Grassland Soc.*, 1955, 10, 139-150. [Nat. Inst. Res. Dairying, Univ. Reading.]

Silage was made from first, second and third cuts of a lucerne-timothy sward. For the first 2 cuts tower silos holding about 15 tons and for the third cut small-scale experimental silos were used. Silage made with additions of glycolic acid, or formic acid for the second cut, molasses, or barley

meal and from the crop without additions but wilted for 24 to 48 hr. were compared. To facilitate distribution of the barley meal the crop was chopped when this addition was used.

The acids and the barley meal gave the best silages, but a subsidiary trial with chopped silage with or without barley meal showed that the quality of the silage was due to the chopping rather than to the barley meal. The wilted silage was well preserved, but compaction was poor and the silage was overheated, with reduced digestibility and the development of moulds. Molasses silage was the least satisfactory, with more butyric acid than the others.—T. D. Bell.

4694

WENTIGER, J. H. and FUNK, K. Untersuchungen über die Silierung von Luzerne unter Beigabe verschiedener Sicherungszusätze. [Ensilage of

alfalfa with different preservatives.] *Arch. Tierernährung*, 1955, 5, 33-40. [Inst. Tierzucht, Martin Luther Univ., Halle, Wittenberg.]

Lucerne harvested in bud was chopped and ensiled with Kofa salt, formic acid or calcium thiocyanate in airtight silos of capacity 2 c.m. After 3 months the Kofa salt silage had 1.40 per cent. lactic acid and a pH value of 4.86 and was considered good; the formic acid silage was of medium quality and the calcium thiocyanate silage bad. Trials with wethers given 2½ kg. silage daily with 400 g. hay showed that the Kofa salt silage had the best starch value but the formic acid silage was equally good in digestible crude protein; the calcium thiocyanate silage was decidedly inferior, and this additive is not recommended.

ANDERSSON, M. and WALKER, A. R. P. Methionine concentration in South African Bantu breast milk. *Brit. J. Nutrition*, 1955, 9, 197-199. [Human Biochem. Unit, S. African Inst. Med. Res., Johannesburg.]

The mean values with standard deviations and ranges for the methionine content of human milk were, for 29 samples from Bantu mothers lactating for from 1 to 27 months, 29.7 ± 5.1 , 19.6 to 39.0, and for 25 samples from South African European mothers lactating for from 2 weeks to 10 months, 26.2 ± 3.2 , 19.3 to 33.4 mg. per 100 ml. The finding for Bantu was significantly higher than for European mothers and provided no evidence in support of the view that a deficiency of methionine may be a cause of kwashiorkor in infants.

PARADISO, M. and LA CAUZA, C. La gonadotropina corionica quale nuovo mezzo per il trattamento dell'eccesso di grasso nel latte umano. [Chorionic gonadotropin as a new

means for treating excess of fat in human milk.] *Riv. Clin. pediat.*, 1954, 54, 122-129. [Clin. Pediat., Univ. Florence.] English and French summaries.

Fat, protein and lactose were estimated in the milk of 20 women before and after 4 intramuscular injections of 500 "units" of chorionic gonadotropin on alternate days. The women were selected as having milk high in fat, the infants of 15 of them having been admitted to the Clinic for eczema or dyspepsia. In 10 of the women the fat value, which ranged from 5.4 to 6.6 per cent. before treatment, fell with treatment to from 3.2 to 3.6. It did not rise again in the next 2 months, 4.4 per cent. in 2 patients being the highest value reached. The other 10 women also showed a fall in the fat value; it did not remain low but could be more or less effectually controlled by further injections. The concentration of protein and lactose was not affected by the injections. The women suffered no adverse effect.—E. M. Hume.

WINZENRIED, H. U. Die Wirkung von Umwelt- und Erbfaktoren auf die Zusammensetzung der Milch mit besonderer Berücksichtigung des MilCHFettes und seiner Bestandteile. [Effect of environment and heredity on the composition of milk with special reference to milk fat and its components.] *Ztschr. Tierzucht. Züchtungsbiol.*, 1955, 64, 105-152. [Inst. Tierzucht., Eidg. Tech. Hochschule, Zürich.]

There is a comprehensive review of the literature, with 118 references. Original work was done in Sweden with 14 pairs of monozygous twin cows studied at different stages of lactation; the study on individual pairs lasted for from 3 to 10½ months and included from 7 to 21 analyses, 205 in all. Variations in the composition of the milk and milk fat were the basis of a statistical study according to methods described by Bonnier and Tédin ("Biologisk Variationsanalys", Stockholm, 1940).

The correlation coefficients between partners of the pairs suggested a strong inherited influence. The values were for protein content + 0.78, sugar + 0.60 and fat + 0.68, and for fat components measured by Reichert Meissl number, Polenske number, iodine number and others they lay between + 0.62 and + 0.89. Between 60 and 80 per cent. of the variation in these characteristics was genetically determined.

The stage of lactation had a greater effect on protein than on other constituents of milk, and was responsible for 31.5 per cent. of its variation. The sugar content varied less with stage of lactation. Of variations in fat content only 10 per cent. were due to stage of lactation.

There was a positive correlation between fat and protein content, $r = + 0.64$.—D. Duncan.

HUNGER, K. and HENRICH, K. G. Ein Beitrag zur Kenntnis der Verteilung des Fettes in der Milch unter besonderer Berücksichtigung der individuellen Unterschiede und Untersuchungen über die Natur der Fettkügelchen an Hand von Dauerpräparaten. [Distribution of fat in milk with special reference to individual differences and studies of the nature of fat globules by means of permanent preparations.] *Ztschr. Tierzucht. Züchtungsbiol.*, 1955, **64**, 333-354. [Inst. Tierzucht., Justus Liebig Hochsch., Giessen.]

The permanent preparations of milk to show fat globules were made by mixing 2 ml. milk and 3 ml. aqueous solution of 2 per cent. sodium citrate and 0.1 per cent. NaOH; after shaking, 2 ml. of this mixture was mixed with 3 ml. of 10 per cent. gelatine and 1 per cent. phenol at 30° C., and a drop was mounted for microscopical examination.

There was a strong positive correlation between the fat content of milk and the size of the globules, $r = + 0.7721$. There was no effect of diet. In mastitis and in cows given large quantities of beet the size increased, but in cows with poor appetites it fell. In 2 cows exercised for an hour the globules were larger at the next 2 milkings and then returned to normal size. An increase in the interval between milkings from 6½ to 12 hr. resulted in an increase of globule size from 15-95 to 21-34 μ . The size depended on the quantity

of milk and the pressure in the udder. The range of fat globules was less in morning than in afternoon and evening milk. In 5 cows the mean size of globules, in μ , was in the morning 15-25, at midday 17-37, and in the evening 16-92. The variation in size was especially wide in the first 10 or 12 weeks after calving, when the largest globules might exceed 40 μ .—D. Duncan.

4700

OOSTHUIZEN, J. C. Daily fluctuations in the fat content of herd milk. *Farming in S. Africa*, 1955, **30**, 49-52. [Coll. Agric., Glen.]

Milk from 36 farms supplying cheese factories was sampled daily for 5 consecutive days to ascertain the extent of variation in fat content. The percentage deviation ranged from 2.7 to 27.6 and reasons for this are discussed in relation to payment on the basis of fat content alone.

J. S. Thomson.

4701

THOMAS, W. R., HARPER, W. J. and GOULD, I. A. Lipase activity in fresh milk as related to portions of milk drawn and fat globule size. *J. Dairy Sci.*, 1955, **38**, 315-316. [Ohio State Univ.]

The total milk from each of 16 cows in different stages of lactation was drawn in 3 portions. The first portion was on the average higher in lipase activity and free fatty acid than the others which did not differ greatly. The size of fat globules increased slightly from the first to the third portion. [In Table 1, columns 6 and 7 are headed fat content instead of initial free fatty acid content, and this is referred to in the text, p. 316, line 3, as initial free fatty content.]—A. Hepburn.

4702

KING, J. O. L. Variations in the quantity and composition of milk yielded by diseased cows while their body temperatures were elevated. *Vet. Rec.*, 1955, **67**, 432-435. [Fac. Vet. Sci., Univ. Liverpool.]

Milk samples from 28 cows under veterinary observation were used in this study. The effects of body temperature on milk composition were considered through the following temperature ranges: 104° F. and over, between 102.5° and 103.9° F., and 102.4° F. and under. The results showed that a rise of temperature was accompanied by a fall of milk yield and solids-not-fat percentage and a rise of butterfat percentage.—J. N. Aitken.

4703

LOPES, C. F. and FILHO, F. S. S. Tipos de leite em São Paulo. [Types of milk in São Paulo.] *Bol. Indúst. animal, São Paulo*, 1954, **14**, 153-163. English summary.

N.A. and R., October 1955

Three grades of pasteurised milk are sold in São Paulo. Grade A is only about 2 per cent. of the total and Grade B 2-6 per cent. Both are whole milks and are produced and pasteurised under good conditions near the city. Grade C milk is produced all over the State, collected at receiving stations, refrigerated and then sent to São Paulo City before it is pasteurised. It is standardised to 3 per cent. fat. Conditions of production are often bad and losses by souring are high.—D. Duncan.

4704

ROGICK, F. A. and LEME DA ROCHA, G. Contribuição ao estudo dos leites ácidos esporadicamente observados no Estado de São Paulo. [Acid milk found sporadically in the State of São Paulo.] *Bol. Indúst. animal, São Paulo*, 1954, 14, 111-121. English summary.

Milk which had been rejected for its high acidity, pH from 5 to 7, was bacteriologically sound. It was high in total solids, solids-not-fat and ash. The cows were at pasture, and the supplementary feeds could not be incriminated in group feeding tests. After 3 weeks the high acidity disappeared spontaneously.—D. Duncan.

Vol. 25, No. 4

korov v zavisimosti ot zhirmolochnosti i stadii laktatzii. [Research into the esterase activity of milk and blood serum of cows and its relation to the fat content of milk and stages of lactation.] *Zh. Obschei Biol.*, 1954, 15, 388-396. [Lab. Biokhim. Vses. Nauch.-Issled. Inst.]

Biochemical investigation of milk and of serum from blood taken from the jugular vein of healthy lactating cows of the same breed suggested that, despite a fairly large degree of individual variation, certain correlations might be assumed. Animals tended to have either low or high values for milk fat, serum lipolytic activity, and content of sulphhydryl compounds in milk. There was also a parallel between blood glutathione and phosphatase activity of milk. Different stages of lactation were marked by alterations in metabolism manifested by changes in alkaline phosphatase in milk and inorganic P and lipase of serum, all of which give values low immediately after calving but rising throughout lactation. Further, animals with milk of high fat content had more reduced vitamin C and sulphhydryl compounds than had those with milk low in fat. Alkaline phosphatase activity and inorganic P content of milk were somewhat higher in animals with milk low in fat than in those with milk high in fat.—D. W. Taylor.

Eggs

4714

HAZEZ, E. S. E., BADRELDIN, A. L. and KAMAR, G. A. R. Egg components in the Fayomi fowl during the first laying year. *Poultry Sci.*, 1955, 34, 400-410. [Fac. Agric., Cairo.]

The weight of whole egg, albumin, yolk and shell of 6663 eggs laid by 50 Fayomi pullets in their first laying year was measured. The results were grouped for consecutive periods of 5 eggs. The average weight of the first egg was 27.8 g., and weight rose at a declining rate to 45.8 g. at the 150th egg. The absolute weight of the components also rose. In the first egg the distribution was albumin 58, yolk 29 and shell 13 per cent. The proportions gradually changed to 51.5, 35 and 12.5 per cent. There were high positive correlations between egg weight and weight of each component, and between the weights of the components. The percentage of yolk in the Fayomi eggs was higher than is reported for other breeds.—T. D. Bell.

Meat (All Kinds)

PRITCHARD, H. and CAWTHORNE, M. The composition of whale-meat meals of various grades. *J. Sci. Food Agric.*, 1955, 6, 148-153. [13 Hamilton Sq., Birkenhead, Cheshire.]

Unofficial commercial grading of whalemeat meals in the United Kingdom is: A, meatmeals,

protein content 80 to 85 per cent.; B, meat-and-bone meals, protein content from 40 to 65 per cent., with more oil and ash than grade A meals; C, mainly bonemeals, but with about 20 per cent. protein and some oil. Analyses of 7 samples in these 3 grades, some from land stations in the southern hemisphere and some from a British floating factory, show that composition is variable but that the crude protein of genuine whalemeat meals is highly digestible by pepsin *in vitro* and contains over 80 or even over 90 per cent. true protein.

Riboflavin, nicotinic acid, pantothenic acid, pyridoxine, inositol and vitamin B₁₂ (cobalamin) were also estimated by methods already described (Abst. 369, Vol. 24); nicotinic acid, vitamin B₁₂ and inositol were more variable than was previously thought. It is stated that the processes now in use reduce riboflavin, pantothenic acid and cystine, but not nicotinic acid, methionine or tryptophan.

Estimations of true protein with Cu, rate of digestion with pepsin, and free fatty acids and peroxide value of oil are suggested as useful criteria of quality and promptness of processing.

HUTCHINSON, J. B. and MARTIN, H. F. The chemical composition of oats. 1. The oil and free fatty acid content of oats and groats. 2. The nitrogen content of oats and groats. *J. Agric. Sci.*, 1955, 45, 411-418; 419-427. [Res. Assoc. Brit. Flour-Millers, St. Albans.]

1. Values are tabulated and analysed statistically for the oil content (extracted with light petroleum, b.p. 40° to 60° C.) of the kernel and whole grain of 10 varieties of spring oats from 22 centres (trial stations of the National Institute of Agricultural Botany and farms in England and Scotland, some represented in more than one season) and 4 varieties of winter oats from 46 centres, and for the free fatty acids of the kernel oil of the same varieties from a smaller number of centres. A special study was made of the oil content of the kernel of Victory oats (174 samples). Another table gives the average oil content of groats from 44 varieties of spring oats and 10 varieties of winter oats.

It was concluded that the oil content may range from 3.5 to 8.0 per cent. on a dry basis, and depends mainly on variety and kernel content (the latter itself a varietal characteristic), though there were indications of slight environmental effects. About 90 per cent. of the oil comes from the kernel, the oil content of which may range from 4 to 11 per cent., with a considerable range within variety. The range was from 5.2 to 7.0 and from 5.9 to 7.3 per cent. for samples of Victory oats from England and Scotland, respectively. The difference was much smaller than is generally supposed by millers and farmers. Acid hydrolysis of the kernel released also about 2.5 per cent. of more complex fatty material. Oat husks contained

under 1 per cent. of oil and about 1 per cent. of complex material. The oil content of groats ranged from 5.0 to 10.1 per cent. according to variety.

The fatty acid content of kernel oil ranges from 3 to 10 per cent. in sound grain and depends much more on environment, including harvest and storage conditions, than on variety.

2. Nitrogen was estimated by the Kjeldahl method in the above samples and others. Values for N content of the kernel, which contains about 95 per cent. of the total N of the grain, are tabulated for 10 varieties of spring oats from 22 centres and 4 varieties of winter oats from 50 centres; some data for newer varieties are included and, finally, N content of the whole grain is given for 20 varieties.

The N content of oat kernels may range from 1.4 to 3.9 per cent. Differences between varieties exist but are much less than those due to environment, and it is suggested that the main factor is the amount of available N in the soil in late spring and early summer. Little difference was found between spring oats and winter oats. For Victory oats grown in England (127 samples) and Scotland (92 samples) the ranges and means were 1.72 to 3.44, 2.43 \pm 0.34 and 1.69 to 2.72, 2.07 \pm 0.22 per cent., respectively. Oat husks contained only about 0.3 per cent. N. When varietal differences were eliminated, a high negative correlation was found between N content and oil content of oat kernels. A smaller negative correlation between N content and kernel weight is ascribed to the tendency in certain drier localities for the oats to ripen before they are fully developed.

SIMS, H. J. The protein content of wheat varieties grown in standard plots and spaced rows. *J. Austral. Inst. Agric. Sci.*, 1955, 21, 38-39. [Dept. Agric., Melbourne, Victoria.]

Although the protein content of a number of wheat varieties was greater when they were grown in rows 14 in. apart than in trial plots of 1/40 acre, the correlation between the results was sufficiently high ($r = +0.89$) to justify the common practice of selecting for protein content from hybrids grown in rows.—W. M. Deans.

KOLOUSEK, J. and COULSON, C. B. **Plant proteins. 2. Amino-acid content of the seed protein of *Trigonella foenum graecum* L. and of the seed protein and thallus protein of *Galega officinalis* L.** *J. Sci. Food Agric.*, 1955, 6, 203-206. [Agrobiochem. Lab., Fac. Agric., Technická 1903, Prague 19.]

The methods of protein extraction and routine analysis were as before (Abst. 2907, Vol. 24); amino-acids were estimated by a rapid method of 2-dimensional chromatography described elsewhere (*J. Sci. Food Agric.*, in the press).

The proteins of galega or goat's rue (*Galega officinalis*, L.), a leguminous plant which contains a poisonous substance and is of uncertain feeding value, do not seem to have been studied before. Galega thallus contained 14.8 per cent. crude protein on a dry basis and galega seed 40.7 per cent., but much of the N could not be isolated as protein; 56 and 70 per cent., respectively, of the total organic N was in the alkali-soluble fraction. In fenugreek (*Trigonella foenum graecum*, L.) seed, on the other hand, protein N formed 47 per cent. of the total N.

The approximate amino-acid composition of the protein of fenugreek seed, galega seed and galega thallus, respectively, was as follows: aspartic acid 9, 4, 5, glutamic acid 9, 10, 5, serine 6, 11, 6, glycine 9.5, 8.7, 6.9, threonine 5, 7, 10, alanine 5.9, 3.6, 7.3, tyrosine 3, 5, 2, histidine 1.1, 5.7, 2.4, lysine 8.0, 5.6, 7.9, arginine 8.0, 5.4, 5.5, phenylalanine 1, 8, 3, leucine 11, 11, 16, proline 1, 4, 4, valine plus methionine 6, 12, 19. The seed proteins show no preponderance of one or two amino-acids.—W. M. Deans.

DALE, A. P. and MEARA, M. L. **The component fatty acids and glycerides of coconut oils.** *J. Sci. Food Agric.*, 1955, 6, 162-166. [Univ. Liverpool.]

Three samples of coconut oils of Indonesian, Solomon Islands and Ceylonese origin were analysed for component fatty acids by the ester fractionation technique. The percentages, by weight, of each acid were, respectively: caproic 0.2, 0.3, nil; caprylic 7.7, 8.1, 7.3; capric 9.7, 8.1, 7.5; lauric 45.0, 46.3, 47.8; myristic 18.0, 17.4, 18.9; palmitic 8.4, 8.6, 7.6; stearic 3.7, 2.0, 2.5; arachidic nil, 1.5, 0.4; oleic 5.8, 5.5, 6.3; linoleic 1.5, 2.2 and 1.7. These data show that the composition of coconut oil does not vary appreciably in widely scattered regions. Systematic crystallisation of the oils from acetone followed by ester fractionation revealed a very complex mixture of mixed triglycerides; only 2 components, myristodilaurin and lauromyristopalmitin, occurred to the extent of over 10 per cent.—G. A. Garton.

- 4736
DALE, A. P. and MEARA, M. L. **The component fatty acids and glycerides of palm-kernel oil.** *J. Sci. Food Agric.*, 1955, 6, 166-170. [Univ. Liverpool.]

Ester fractionation showed a specimen of palm kernel oil to consist of the following fatty acids: caprylic 2.4, capric 3.7, lauric 45.2, myristic 18.6, palmitic 8.5, stearic 2.5, arachidic 1.9, oleic 15.1 and linoleic 2.1 per cent. by weight. The major component glycerides were shown to be myristodilaurin 27.2, caprolauro-olein 12.2 and lauro-myristo-olein 10.6 per cent.—G. A. Garton.

- 4737
TAYEAU, F., FAURE, F., SÉCHET-SIRAT, J. and LÉVY, G. **Sur la valeur alimentaire des protéines de la graine de soumpe (*Balanites aegyptiaca* Del.). [Food value of the proteins of Egyptian balsam seed (*Balanites aegyptiaca*, Del.).]** *C. R. Acad. Sci.*, 1955, 240, 1481-1483.

From the seeds of the edible fruit of Egyptian balsam (*Balanites aegyptiaca*, Del.), a tree of the Simarubaceae family which grows in tropical regions, notably French West Africa, an excellent oil is obtained, and the residual cake contains about 50 per cent. protein. Chromatography of an acid hydrolysate of the protein indicated that it contained the following percentages of amino-acids: aspartic acid 19, glutamic acid 25, glycine 17.3, alanine 1.5, valine 2.5, serine 9.5, proline 2, threonine 2. The following were found by chemical methods: cystine 1.8, methionine 1.7, phenylalanine 2.9, tyrosine 1.8, tryptophan 0.9, histidine 1.8, arginine 4.5, lysine 5.2, and leucine 3.8, isoleucine 2.8 were found by the microbiological method of Lévy and Polonovski (*Bull. Soc. Chim. biol.*, 1952, 34, 221). The percentage digestibility of the protein was 47, slightly less than that of groundnut protein. Although the seed protein is low in methionine, isoleucine, lysine, threonine, valine and tryptophan, it may serve as a useful protein supplement to the diet, since the tree grows in regions where protein is scarce.—W. M. Deans.

WHITE, P. L., ALVISTUR, E., DÍAS, C., VIÑAS, E., WHITE, H. S. and COLLAZOS, C. Nutrient content and protein quality of quinoa and cañihua, edible seed products of the Andes Mountains. *J. Agric. Food Chem.*, 1955, 3, 531-534. [Dept. Nutric., Minist. Salud Pub. Asist. Soc., Lima.]

Quinoa (*Chenopodium quinoa*) and cañihua (*C. pallidiculae*) are widely grown in the Andes. For their seeds analytical data corrected to 12 per cent. moisture are, respectively, per 100 g., protein (N \times 6.25) 11.0, 14.1; ether extract 5.3, 4.1; fibre 4.9, 10.7; ash 3.0, 4.6 g., and Ca 131, 126; P 424, 461; Fe 6.8, 18.8; vitamin B₁ 0.52, 0.78; riboflavin 0.31, 0.55; nicotinic acid 1.60, 1.34 mg. Except for phenylalanine, which is lower, they are similar to wheat in their contents of essential amino-acids.

The results of 3 types of feeding experiment with rats indicated that both by themselves and in comparison with dried skimmed milk powder the seeds had high feeding value. In the districts in which they are produced they would be valuable additions to the vegetarian diets of the Indian population.—D. Harvey.

4739

WIGGINS, L. F. and WILLIAMS, J. H. Amino acid content of West Indies sugar cane. *J. Agric. Food Chem.*, 1955, 3, 341-345. [Dept. Sugar Chem. Technol., Imp. Coll. Trop. Agric., Trinidad, B.W.I.]

Sugar cane juice contained 11 amino-acids. The total content decreased with maturity, but drought

caused a marked increase, and a less pronounced increase in sucrose. Quantitative differences between varieties may have been due to environmental conditions such as availability of water. Sugar cane leaves contained the same amino-acids, but most of the nitrogen was in protein form.

A. Hepburn.

4740

HOLDT, M. M. V., LIGTHELM, S. P. and NUNN, J. R. South African seaweeds: seasonal variations in the chemical composition of some Phaeophyceae. *J. Sci. Food Agric.*, 1955, 6, 193-197. [Nat. Chem. Res. Lab., S. African Council. Sci. Indust. Res., Pretoria.]

Seasonal variations in the composition of 3 brown seaweeds (*Echlonia maxima*, *Laminaria pallida* and *Bifurcaria brassicaeformis*) from 3 places on the Cape Peninsula are shown graphically and in tables. Organic N was very constant. Mannitol in the fronds tended to be higher in winter than in summer. Little laminarin was found except in the fronds of *E. maxima* and it also was higher in winter than in summer. Alginic acid in the fronds of *E. maxima* and *L. pallida*, on the other hand, was higher in summer than in winter. Ash in these species had a maximum in mid-winter (June); that of *B. brassicaeformis* fluctuated irregularly. The variations do not follow the regular patterns found in Scotland, possibly owing to the more constant sea temperature and light intensity in South Africa.

REITH, J. W. S. Effects of calcic and magnesian liming materials on the calcium and magnesium contents of crops and pasture. *Empire J. Exp. Agric.*, 1954, 22, 305-313. [Macaulay Inst. Soil Res., Aberdeen.]

The 2 types of lime applied at from 1 to 2 tons per acre had little effect upon the Ca or Mg content of the root portion of mangold, fodder and sugar beet, swede or turnip, or on kale stems or barley and oat grain. Magnesian limestone increased the Mg content of the root tops, kale leaves and cereal straw, and doubled the Mg content of hay,

N.A. and R., October 1955

also raising Ca by about 20 per cent. Over a 3-year period there was a mean increase in the Mg content of mixed herbage of 55 per cent. over the no-lime or ground limestone treatments, but little effect on Ca. Mg and Ca contents of pasture showed a 60 to 100 per cent. variation during the growing season, rising from the lowest point in mid-May to the highest level during the period August to October.—J. L. Corbett.

4743

WALKER, T. W., ADAMS, A. F. R. and ORCHISTON, H. D. The effects and interactions of sulphur, phosphorus, and molybdenum on the growth and composition of clovers. *N.Z. J. Sci. Technol.* [A], 1955, 36, 470–482. [Canterbury Agric. Coll., Lincoln.]

Trials with CaSO_4 on poor sandy and silty loams in the Canterbury foothills, mainly at altitudes of 1400 ft., showed that S, with P, is necessary for establishment and growth of clover except on one soil where gypsum reduced the clover yield. This effect is attributed to increased Mn uptake and consequent Mn—Mo antagonism, Mo being necessary for N fixation. Thus trials of P fertilisers should include studies of the content of S, which is most needed during the phase of organic matter accumulation under pasture. Applications of 4 oz. Na molybdate per acre had no effect on first-year clover growth but increased Mo in the herbage to levels possibly hazardous for grazing animals.

J. L. Corbett.

4744

MITCHELL, R. L. Trace elements in some constituent species of moorland grazing. *J. Brit. Grassland Soc.*, 1954, 9, 301–311. [Macaulay Inst. Soil Res., Craigiebuckler, Aberdeen.]

Results are given of an extensive investigation of the trace element content of hill grazing in 2 areas in Sutherland from 1946 to 1948, during which period herbage was sampled 10 times. In addition samples of *Narthecium ossifragum*, *Carex panacea*, *Anthoxanthum odoratum*, *Scirpus caespitosus*, *Molinia caerulea* and *Calluna vulgaris* were analysed. The trace elements investigated spectrographically were Co, Mo, Fe, Mn, Zn, Pb, Sn, Cu, Ti, Ba and Sr.—J. S. Thomson.

4745

PRICE, N. O., LINKOUS, W. N. and ENGEL, R. W. Minor element content of forage plants and soils. *J. Agric. Food Chem.*, 1955, 3, 226–229. [Virginia Agric. Exp. Stat., Blacksburg, Va.]

From 2 counties of Piedmont, Virginia, 88 samples from 4 types of soil and 153 samples of forages from the same localities, mainly alfalfa and lespedeza, were analysed for B, Co, Cu, Mn, Mo and Zn. B was estimated by the quinazalin method of Berger and Truog (Abst. 3952, Vol. 9),

Co by the method of Beeson (*J. Assoc. Off. Agric. Chem.*, 1953, 36, 405), Cu, Mn and Zn by A.O.A.C. methods and Mo by the method of Evans *et al.* (Abst. 4659, Vol. 20) for plants and that of Robinson (*Soil Science*, 1948, 66, 317) for soils. The results are tabulated and show great variations for soils, less marked but still considerable variations for plants. There was a tendency for high soil values to be associated with high plant values, but in only one instance, Co content of alfalfa grown on one particular soil type, was the correlation highly significant. The results are discussed in conjunction with the literature on the requirements of grazing animals and it was concluded that forages in the region studied contain adequate amounts of the trace elements, except in a few areas where they are low in Co and Cu.—W. M. Deans.

4746

BASSETT, E. G. and WHITE, E. P. Oestrogens and New Zealand dairy pastures. *N.Z. J. Sci. Technol.* [A], 1955, 36, 485–492. [Ruakura Animal Res. Stat., Dept. Agric., Hamilton.]

The literature is briefly summarised. To test the idea that the stimulation of milk production by spring pasture may be due to oestrogens, samples were taken by the frame method weekly from August to December from 2 adjacent paddocks each used by 50 cows, one grazed rotationally and the other as night paddock. Extracts made by a modification of Robinson's method for subterranean clover (Abst. 3133, Vol. 19) were tested by the method of Evans *et al.* (*Endocrinology*, 1941, 28, 747); 4 mice each had the equivalent of 7 g. pasture, wet weight. Grasses, clover and other leguminous plants, and weeds, 31 species in all, were also tested separately.

No oestrogen was found in any sample of pasture or in individual species; but samples of subterranean clover in early flowering and flowering stages from another locality did show activity, and the leaves of red clover were almost as potent, though 6 ewes grazed on a red clover sward were successfully mated (*ibid.*, p. 437).

The lactation curves of the 2 groups of cows showed peaks of production clearly coinciding with the different periods of lush growth in the 2 paddocks, and the suggestion is made that the sudden change in feed may stimulate the ovaries of the animals themselves to produce additional oestrogens. A sudden increase in teat length of calves associated with a sudden flush of grass is also reported, though again no oestrogen could be detected in the grass.—W. M. Deans.

4747

HARTFEL, W. Der Einfluss von Natrium- und Kaliumdüngung auf den Mineralstoffgehalt von Futterpflanzen. [Effect of fertilising with sodium and potassium on the

mineral content of fodder plants.] *Arch. Tierernährung*, 1955, 4, 349-356. [Inst. Tierzucht, Univ. Bonn.]

There is evidence that animal diseases, notably grass tetany of cattle, may arise from a faulty K:Na ratio in feed or pasture. Preliminary experiments with oat and ryegrass seedlings in pots showed that Na content and K content could be raised by fertilising with Na or K sulphate. Adding Na did not affect K content, and vice versa. There were indications that K was favourable to Ca uptake and Na unfavourable. In larger pots, yield was better with K or a mixture of Na and K than with Na, and adding Na slightly reduced K content and vice versa. Similar but less marked results were obtained from a plot experiment with 4 replicates of 12 treatments. Work is continuing. W. M. Deans.

SQUIBB, R. L., MÉNDEZ, J., GUZMÁN, M. A. and SCRIMSHAW, N. S. Ramie—a high protein forage crop for tropical areas. *J. Brit. Grassland Soc.*, 1954, 9, 313-322. [Inst. Agropecuario Nac., Guatemala.]

Samples of ramie (*Boehmeria nivea*) cut when the plant had grown to a height of 5, 10, 15, 20, 25, 30 and 35 in. were analysed for total nitrogen, ether extract, crude fibre, carotenoids, ascorbic acid, some minerals, members of the vitamin B complex and amino-acids. Vitamin A and carotenoids in ramie meal were also investigated by chick growth and blood tests. The plant was high in crude protein, which decreased slightly as the height increased. Crude fibre followed an opposite trend. P and ascorbic acid declined throughout the growing period. Fe and carotenoids declined till the plant had grown to a height of 25 in. and then remained constant. The variations in components of the vitamin B complex were not related to the stage of growth. Lysine decreased till 25 in. and then remained constant, tryptophan decreased constantly and methionine decreased till 20 in. and then increased to above the initial levels at 35 in. The trials with ramie meal showed that it was a good source of vitamin A and carotenoids. Ramie as a forage crop compares favourably with

alfalfa, particularly in the tropics, where it is more suited to the climate and conditions.—T. D. Bell.

4750

ULVESLI, O. Kvaliteten av høyavlinga 1954. [Quality of hay harvested in 1954.] *Forskning og Forsøk Landbruken*, 1955, 6, 79-89. [Norges Landbruks Høgskole.] English summary.

Data are given for the composition in terms of crude botanical composition, dry matter, protein, fibre, digestibility in 10 tests with 5 samples, computed feeding value, Ca, P and carotene, of 3 samples of hay from East and 1 each from West Norway and Trøndelag. The results are not considered to be representative of Norwegian hay, but since the samples are taken year by year from the same farms in the same way, they throw some light on year to year variations.—I. Leitch.

GOLDSCHMIDT, S. and BURKERT, H. Über das Vorkommen einiger in Bienenhonig bisher unbekannter Zucker. [On the occurrence in honey of some hitherto unknown sugars.] *Hoppe-Seyler's Ztschr.*, 1955, 300, 188-200. [Inst. Org. Chem., Tech. Hochsch., Munich.]

A honeydew honey contained glucose 31.4 and fructose 33 per cent. Paper chromatography of a concentrated solution, by methods described, showed the presence of appreciable quantities, from 0.5 to 2 per cent., of maltose, isomaltose, and the trisaccharides raffinose and kestose, and traces of sucrose, erlose, melezitose (reported by other workers to occur in quantity in this type of honey), dextrantriose, 4-glucosyldextrantriose and a higher carbohydrate of dextrin type. Results for 2 ordinary honeys were similar but in 3 others the higher sugars were not detected. In winter honey derived from sugar syrup, only sucrose, maltose, isomaltose and erlose were found. It is believed that sucrose, kestose, melezitose and raffinose come from the nectar but that maltose, isomaltose, erlose and dextrantriose arise from transglucosidation in the bee's body.—W. M. Deans.

QUATTRIN, N., JACOPO, G. and BRANCACCIO, A. Vitamine e metabolismo dei sulfamidici. [Vitamins and sulphonamide metabolism.] 1. Comportamento del tasso sulfamidico in liquidi e tessuti di cavia dopo carico con vitamine del gruppo B e C. [1. Sulphonamide values in body fluids and tissues of guineapigs after administration of vitamins of the B group and vitamin C.] 2. Sull'acetilazione dei sulfamidici dopo carico con vitamine del gruppo B e C. [2. Acetylation of sulphonamides after administration of vitamins of the B group and vitamin C.] *Acta vitaminol.*, 1955, 9, 17-23; 51-56. [Ist. Semeiotica Med., Univ. Naples.] French, English, German and Spanish summaries.

1. Groups of guineapigs were injected subcutaneously with doses of about 500 mg. per kg. bodyweight of sulphacetamide, sulphisoxazole or sulphone N-acetate. The concentration of the drugs, total and in the free state, was estimated in the body fluids and tissues of animals not given, or given half an hour later, an injection of one of 6 vitamins. The animals were killed 1½ hr. after

the injection of the drug. There was some increase in the concentration of sulphacetamide and of sulphone N-acetate after administration of pyridoxine or panthenol or ascorbic acid; particularly marked was the effect of pyridoxine, which increased the concentration of both drugs, total and free, in the lungs, liver, kidneys, brain, blood and urine. In the bile there was an increase with pyridoxine in the concentration of sulphacetamide but not of sulphone N-acetate. There was little effect of any vitamin on the concentration of sulphisoxazole, or of vitamin B₁, riboflavin or nicotinamide on the concentration of the other 2 drugs.

2. With the same technique, the effect on acetylation of the same 3 substances was tested with the same vitamins. By the action of riboflavin and pyridoxine some increase was caused in the acetylation of sulphone N-acetate, very little in that of sulphacetamide and none in that of sulphisoxazole, but the result was not conclusive.

BUTTURINI, U. and CASA, G. Modificazioni indotte dall'acido ascorbico, dal tocoferolo e dal bleu di metilene sugli anticorpi antistreptolisini. [Modifications produced by ascorbic acid, tocopherol and methylene blue on antistreptolysin antibodies.] *Acta vitaminol.*, 1955, 9, 65-69. [Ist. Patol. Spec. Med., Univ. Bologna.] French, English, German and Spanish summaries.

Groups of 2 or 3 guineapigs were given a single injection of O-Streptolysin, while at the same time being given daily intramuscular injections of wheat germ oil or α -tocopherol or methylene blue or vitamin C. The titre of antistreptolysin in the blood was estimated up to the 9th day after the injection of streptolysin. The formation of antistreptolysin was inhibited or greatly reduced in most of the animals treated with vitamin E or C or methylene blue. When α -tocopherol was given after a high titre of antistreptolysin had been established, the titre was immediately reduced to nil.—E. M. Hume.

HILL, C. H., GARREN, H. W., KELLY, J. W. and BARBER, C. W. Influence of high levels of vitamins on resistance of chicks to fowl typhoid. *Proc. Soc. Exp. Biol. Med.*, 1955, 88, 535-537. [Dept. Poultry Sci., North Carolina State Coll., Raleigh.]

Resistance of 4-week-old chicks to infection with *Salmonella gallinarum* was increased when vitamins were added to the basal diet to give a tenfold excess over requirements. The effects of the vitamin B complex, the fat-soluble vitamins A, D, E and K, and vitamin C were investigated separately but there was no increase in resistance unless all known vitamins were given. Possible explanations of the protective effect of excessive amounts of vitamins are discussed and further studies are planned.—A. M. Copping.

LUCKEY, T. D., PLEASANTS, J. R. and REYNIER, J. A. Germfree chicken nutrition. 2. Vitamin interrelationships. *J. Nutrition*, 1955, 55, 105-118. [Lobund Inst. Res. Life Sci., Univ. Notre Dame, Ind.]

For part 1 see Abst. 1675, Vol. 20.

Groups of germ-free and conventionally reared chicks were given synthetic rations complete or deficient in vitamin B₁, riboflavin, nicotinic acid, biotin, folic acid or vitamin K, and the concentration of the B vitamins in liver and caecum was studied. There was no difference between germ-free and conventionally reared birds in metabolism or requirements of the B vitamins, but the reaction to deficiency of vitamin B₁, riboflavin, nicotinic acid and folic acid was more acute in the germ-free. Birds showing signs of deficiency had in their excreta sufficient vitamins for protection had they been able to utilise them. There was no evidence that microbial synthesis in the caecum was responsible for the presence of the vitamins in the excreta, since they occurred equally in the germ-free and the conventionally reared chicks. Germ-free chicks were able to recover spontaneously from the effects of dietary vitamin K deficiency.—T. D. Bell.

BRÜGEMANN, J., DREPPER, K. and TIEWS, J. Studien über die Verdauungsphysiologie des Schweines. 1. Bilanzuntersuchungen von Calcium, Phosphor, Jod, Vitamin A, Carotin, Vitamin B₁ und Gesamtnikotinsäure an wachsenden Schweinen bei gleichzeitiger Durchführung einer Gesamtnährstoffbilanz. [Physiology of digestion in pigs. 1. Balance experiments with calcium, phosphorus, iodine, vitamin A, carotene, vitamin B₁ and total nicotinic acid in growing pigs with simultaneous total metabolic balance.] *Arch. Tierernährung*, 1954, 4, 133-143. [Inst. Physiol. Tiere, Univ. Munich.]

The pigs were 4 castrated males from 2 litters and at the beginning of the study they were 17 and 19 weeks old. One from each litter was a runt and had a poor appetite, intestinal catarrh, slight pustular dermatitis on the back and thighs and signs of tetany. Two 5-day balance studies were made after preliminary periods of 14 and 9 days, and then, after another 9-day interval, six 2-day balances. On the first of these days a single subcutaneous or intramuscular injection was given of 100 mg. nicotinamide, 10 mg. vitamin B₁, 1.8 g. Ca (as the gluconate) with 1.1 g. P (as Tonophosphanforte), 36,000 I.U. vitamin A, or 764.45 mg. I (as KIO₃).

The initial diet, in g. per head daily, was barley-meal 250 (milo in the third experiment), wheat bran 250, lucerne meal 50 and steamed potatoes to appetite, with 2½ litres skimmed milk as protein supplement. During the 3 balance periods the potatoes were limited to 2, 3 and 4 kg. daily as the pigs grew. They were fed twice daily. The mean weights of the pigs in the 3 balance periods were 30.5, 37.5 and 46.5 kg.

Balance results are given fully in tables. All balances were positive and the unthrifty pigs approached their littermates in weight and condition as the experiment advanced. Retention, as a percentage of intake of crude protein, declined in both members of a pair as the pigs grew. Total digestibility of the ration was less good in the runt pigs to begin with, but almost as good as in the healthy pigs by the last period. Runts retained less Ca, P, phytin P and vitamin B₁ than their littermates. Retention of Ca, P and phytin P increased with growth. Retention of I and carotene was similar in healthy and runt pigs; per kg. bodyweight, I retention fell with age, but carotene retention was steady. Absolute and relative retention of total nicotinic acid increased with growth.

Runts had higher blood sugar and nicotinic acid than normal pigs, but lower blood I.

Injection of nicotinamide increased loss of vitamin A by 5 per cent. Vitamin B₁ increased

excretion of I, but halved that of nicotinic acid and decreased that of Ca by 12 per cent. and loss of vitamin A by from 3 to 9 per cent. Runts excreted less of the injected vitamin B₁. Injection of Ca and P increased loss of vitamin A; vitamin A reduced excretion of nicotinic acid in faeces by 40 per cent. and increased the retention of nutrients generally.

It is concluded that runt pigs have no typical mineral or vitamin deficiency, but a general disturbance of digestion.—D. Duncan.

STEINEGGER, P. and MENZI, M. Versuche über die Wirkung von Vitamin-Zusätzen nach Verfütterung von Adsorbentien an Mastpoulets. [The effect of vitamin supplements after administration of adsorbents to fattening chickens.] *Arch. Geflügelk.*, 1955, 19, 165-176. [Schweiz. Lehr- und Versuchsanst. Geflügelzucht, Zollikofen-Berne.] English summary.

In a preliminary experiment with chicks up to 12 weeks of age, the addition of charcoal or a commercial adsorbent to an adequate practical ration had no significant effect on weight gain or efficiency of feed utilisation. In the third week, however, severe feather-picking and cannibalism occurred in the groups having the adsorbents. In a further experiment, 112 of the chicks which had suffered severe feather-picking were removed from the brooder house into fattening cages and given the basal diet alone, or supplemented with vitamins or charcoal or both or the commercial adsorbent. Feather-picking and cannibalism ceased in all the groups, showing that they were due to environmental conditions and not to diet.

MORTON, R. A. and BRO-RASMUSSEN, F. Comments on the determination of vitamin A in natural products and especially cod-liver oils. *Analyst*, 1955, 80, 410-418. [Dept. Biochem., Univ. Liverpool.]

The estimation of vitamin A by spectrophotometric methods is discussed in relation to the problems arising out of the presence of neovitamin A₁ and vitamin A₂ as well as of all-*trans*-vitamin A₁ in fish liver oils. Tables are presented of the properties of all-*trans*- and neovitamin A₁ and vitamin A₂ alcohols, and of conversion factors to give aggregate vitamin A activity for mixtures of all-*trans*-vitamin A₁, neovitamin A₁ and vitamin A₂, for solutions in ethanol and cyclohexane. Results are given of analyses at Liverpool and Copenhagen of 3 cod liver oils and 2 richer oils. At Liverpool, vitamin A₂ was estimated by the Carr Price method with correction for neovitamin A₁ by the nine-point correction method of Cama *et al.* (Abst. 4695, Vol. 21). At Copenhagen the method of Bro-Rasmussen *et al.* (see following Abst.) was used for chromatographic separation and estimation of the 3 vitamin A alcohols. It is considered that the two sets of results were in good agreement considering the complexity of the problem.—R. J. Ward.

4765

BRO-RASMUSSEN, F., HJARDE, W. and POROTNI-KOFF, O. Chromatographic separation of vitamin-A-active compounds in cod-liver oil. *Analyst*, 1955, 80, 418-428. [Statens Vitamin Lab., Copenhagen.]

Vol. 25, No. 4

Neovitamin A, all-*trans*-vitamin A₁ and vitamin A₂ in cod liver oil were separated satisfactorily on a column of specially prepared dicalcium phosphate 50 cm. long and 3 cm. in diameter, and were eluted with a 16:1 v/v mixture of light petroleum and ether and collected in 15-ml. fractions. The spectral absorption curves of the compounds so separated showed good agreement with those for the pure substances obtained from a crystalline neovitamin A preparation, by chromatographic purification from synthetic vitamin A₁, and by chromatographic isolation of vitamin A₂ from carp liver.—R. J. Ward.

LORD, J. W. and BRADLEY, P. M. A modified method for the spectrophotometric determination of vitamin A in margarine. *Analyst*, 1955, 80, 429-438 (with discussion 438-441). [Res. Dept., J. Bibby and Sons, Ltd., Liverpool 3.]

Improvement in the precision of the Carr Price test for estimating vitamin A in margarine was obtained by purifying the unsaponifiable fraction on a column of defatted bonemeal 3 cm. long and 3 cm. in diameter. Light petroleum, b.p. 40° to 60° C., alone or with 5 per cent. ether added, was used to remove pigments, and the vitamin A was removed from the column with acetone. The procedure did not, however, remove substances that had general absorption greatly distorting the absorption band of vitamin A in the ultraviolet region. For estimating vitamin A by its ultraviolet absorption, the unsaponifiable fraction was

subjected to chromatography on a column of defatted bonemeal 25 cm. long and 1 cm. in diameter. The carotene or dye from the margarine was eluted with light petroleum, b.p. 80° to 100° C., and the vitamin A was eluted with light petroleum containing 16 per cent. ether. The eluate was collected in 5-ml. portions and samples were taken from those containing vitamin A, which were identified by testing 0.4-ml. portions of them with the Carr Price reagent. Readings were taken at 315, 325 and 335 m μ . and a simple correction was applied. The method gave results which compared favourably with the official method (*Statutory Instruments*, 1954, No. 613).—R. J. Ward.

SPRUYT, J. P. Accelerated stability test for vitamin A in oils and fats by means of surface-enlarging at room temperature. *J. Amer. Oil Chem. Soc.*, 1955, **32**, 197-200. [Food Products Dept., N.V. Philips-Roxane, Weesp, Holland.]

A rapid test is described for the stability of vitamin A in oils; it reproduced ordinary storage conditions in an accelerated procedure. Rapid oxidation was secured by spreading the oil over glass beads to give a surface about 60 times the original. The progress of oxidation was followed by estimating the vitamin A in the oil at intervals with the SbCl₅ method. About 0.06 g. oil was weighed into a petri dish and dissolved in light petroleum (40° to 60° C.). About 4 g. specially cleaned glass beads of diameter about 2.2 mm. were then added to cover the bottom in a level layer, and the light petroleum was evaporated at room temperature in the dark. Dishes so prepared were kept in an oven at 20° C. for different times. From estimations of vitamin A the time in days was found which the vitamin A content took to fall to 50 per cent. of the original. Halfway values are presented for a number of different oils and synthetic vitamin A preparations. Comparative tests were made with Swift's activated oxygen method, and some striking differences between the methods were found.—I. M. Sharman.

MOORE, T. and MITCHELL, R. L. Dental depigmentation and lowered content of iron in the incisor teeth of rats deficient in vitamin A or E. *Brit. J. Nutrition*, 1955, **9**, 174-180. [Dunn Nutrit. Lab., Univ. Cambridge.]

Albino and piebald rats were maintained on purified diets lacking in vitamin A or vitamin E. In order to produce chronic vitamin A deficiency small doses of 28 I.U. a week were given as vitamin A acetate. The teeth of the albino rats were almost completely white after 40 days without vitamin E, but in the piebald rats depigmentation was delayed even for 9 months. Deficiency of vitamin A caused depigmentation of the teeth in both strains; the change of colour often appeared after curative doses of vitamin A had been begun and was presumably due to emergence of that part of the tooth which had been formed during the period of deprivation.

The white enamel contained less than from 0.02 to 0.03 per cent. Fe, compared with from 0.07 to 0.27 per cent. in the normal enamel. The content of Fe in the dentine and of Mn in the enamel and dentine was too low for estimation by the method of flame spectrophotometry used.—A. M. Copping.

MIGICOVSKY, B. B. Inhibition of cholesterol formation by rat liver homogenates. *Canad. J. Biochem. Physiol.*, 1955, **33**, 135-138. [Div. Chem., Sci. Serv., Dept. Agric., Ottawa.]

N.A. and R., October 1955

The synthesis of cholesterol by rat liver was measured by incubating homogenates with ^{14}C -acetate, precipitating the cholesterol with digitonin, and measuring the activity of the digitonide in a gas flow counter. No synthesis was detected in homogenates from the livers of rats which had been kept on a diet deficient in vitamin A or starved for 48 hr. and the same homogenates inhibited cholesterol formation when they were added to homogenates from normal livers. The inhibitory power could be demonstrated in both the supernatant and the residual fraction prepared from the abnormal homogenates by centrifuging.

PLANEL, H., SARDOU, R. and GUILHEM, A. Étude expérimentale de l'action de la vitamine A sur les épithéliums digestifs du rat. [Experimental study of the action of vitamin A on the digestive epithelia of the rat.] *C.R. Soc. Biol.*, 1955, 149, 199-201.

Young rats were killed after being kept for from 45 to 116 days on a diet deficient in vitamin A. Such deprivation did not cause metaplasia in the simple cylindrical epithelium lining the intestines, but in the oesophagus and fore-stomach there was some disturbance in the keratinisation of the lining, which did not amount to metaplasia. Intramuscular injection of 30,000 I.U. vitamin A, given every other day for 80 days, had no effect on the epithelium of the intestinal tract.—T. Moore.

HELGEBOSTAD, A. Eksperimentell A hypervitaminose hos pelsdyr. [Experimental excess of vitamin A in fur animals.] *Nord. Vet.-Med.*, 1955, 7, 297-308. [Norges Vet.-Høgsk., Forsøksgard, Pelsdyr, Heggedal.] English and German summaries.

If a fox was fed on ungutted fish only, it would require 300 or 400 g. daily to cover its protein requirements and that amount would contain from 15 to 20 g. oil, mostly liver oil. With coal-fish that would represent about 3.5 I.U. vitamin A and the question of vitamin A excess does not appear to arise. Yet signs attributed in laboratory animals to poisoning with vitamin A are not uncommon in fur animals.

Experiments are described in which 15 foxes, 3 mink and 2 Siberian mink were given by injection an emulsion with Tween 80 in physiological saline

Vol. 25, No. 4

of a cod liver oil concentrate or by mouth the concentrate containing 800,000 I.U. vitamin A per g., diluted 1 in 3 with arachis oil.

Both fox and mink tolerated 40 I.U. vitamin A per g. bodyweight daily without disturbance for 3 or 4 months. Fully grown animals could take from 200 to 300 I.U. per g. bodyweight daily for from 6 to 8 weeks but young animals were affected in a shorter time. Signs of excess were anorexia, bone changes with exostoses, decalcification and spontaneous fractures, loss of fur, exophthalmos, cramp and local hyperaesthesia of the skin.

CLARK, I. and COLBURN, R. W. A relationship between vitamin A metabolism and cortisone. *Endocrinology*, 1955, 56, 232-238. [Merck Inst. Therap. Res., Rahway, N.J.]

The vitamin A content of the livers of rats kept on a stock diet and injected with 3 mg. cortisone daily for 21 days was 307 μg . The mean value for pair-fed untreated rats was 449 μg . and for untreated rats fed to appetite 625 μg . The kidneys of the respective groups contained 5, 10 and 21 μg . vitamin A. The livers of stock rats which were given daily from 500 to 800 "units" of vitamin A and 3 mg. cortisone contained 3790 μg ., pair-fed rats not given cortisone 5386 μg ., and rats fed to appetite and not given cortisone 4508 μg . The vitamin A content of the kidneys of the respective groups was 20, 26 and 35 μg . When male rats were given a diet deficient in vitamin A with 3 mg. cortisone daily the vitamin A content of the liver fell from an initial value of 55 μg . to one of 11 μg . after 13 days. The vitamin A content of the liver

of deprived rats, not given cortisone and fed to appetite, remained constant throughout the 13 days. In a third experiment rats were kept on a deficient diet for 20 days with 3 mg. cortisone daily; rats not given cortisone were pair-weighted as controls. For the last 6 days rats from each group were given 60 μ g. β -carotene daily. The vitamin A content of the liver of the cortisone-treated animals fell from an initial value of 36 μ g. to 0 after 15 days and there was no increase after carotene was given; in the pair-weighted controls it fell from 36 to 3.9 μ g. after 15 days and to 3.5 after 20 days. The carotene content of the livers rose to 12.9 μ g. from an initial value of 6.3 in the cortisone-treated group, and remained constant in the pair-weighted controls.

To study the effect of cortisone on conversion of β -carotene to vitamin A, 4 groups of rats were given 400 μ g. carotene daily; one group was given 3 mg. cortisone daily, one group was pair-weighted to the first group, one group was pair-fed to the first group, and one group was given no cortisone and fed to appetite. After 10 days the total vitamin A content of the livers of rats in the 4 groups, respectively, was 507, 428, 545 and 687 μ g., and after 20 days 717, 724, 776 and 838 μ g. The total carotene content after 10 days was 7.3, 4.3, 5.1 and 4.2 μ g., and after 20 days 11.2, 6.2, 5.5 and 5.2 μ g.

Adrenalectomized rats maintained on a daily dose of 0.5 mg. deoxycorticosterone acetate were given a diet deficient in vitamin A with 100 μ g. carotene 3 times a week for 10 days with or without an injection of 1.5 mg. cortisone daily for 15 days. The animals not given cortisone were pair-weighted to the cortisone group. The total vitamin A in the livers of the rats in the cortisone-treated group was 167 μ g. after 5 days, 101 after 10 days and 64 after 15 days, compared with 167, 156 and 174 μ g. for the pair-weighted controls not given cortisone.—R. J. Ward.

LE GALLIC, P. Précisions nouvelles sur l'activité vitaminique A présentée par les mélanges de caséine et de saindoux dans une ration équilibrée. [New data on the vitamin A activity of mixtures of casein and lard in a balanced ration.] *C.R. Soc Biol.*, 1955, 149, 65-68.

Mice were kept for 37 days on a diet deficient in vitamin A, which contained peptone, starch and dried yeast, and some of them were then given for 4 days a diet containing casein and lard. Livers from such mice were given to rats deficient in vitamin A. From the growth response to 2 livers it was calculated that the liver of mice that had had the diet without lard contained 5 I.U. per liver, but that the livers of those that had had the diet with casein and lard contained 15 I.U. per liver.

Such a content seemed too great to be explained by the presence of vitamin A as such in the lard, and the high value is taken as evidence that a balanced diet containing casein and lard promotes the formation of a chemically unidentified "vitamine A-hormone". (See Absts. 1620, 3345, Vol. 20.)

BIERI, J. G. Effect of tocopherol on carotene conversion. *Proc. Soc. Exp. Biol. Med.*, 1955, 88, 482-484. [Dept. Biochem. Nutrit., Univ. Texas Med. Branch, Galveston.]

Weanling rats were given a diet deficient in vitamin A alone for 10 days, and then for another 5 days alone or with supplements of 4, 10 or 20 mg. α -tocopherol daily. On the 18th day, when about half the animals had ceased to gain weight, a single dose of 13.6 μ g. of an aqueous dispersion of β -carotene in Tween 40 was injected into the tail vein. Eighteen days later the mean weight gains of the 4 groups were 43.7, 48.1, 46.3 and 49.5 g., respectively. In another experiment the supplements were of 0.01, 0.05 and 0.10 mg. β -tocopherol with a single injection of 12.3 μ g. of α -carotene. The weight gains 15 days after injection were 52.7, 55.3, 48.0 and 50.0 g., respectively. In a third experiment 2 groups of rats were depleted of vitamin A and one group was given 20 mg. α -tocopherol by mouth daily for 3 days. Seven days later both groups were given a single injection of 88 μ g. β -carotene per 100 g. bodyweight, and 24 hr. later they were killed. The combined livers and kidneys of the groups, respectively, had, on the average, per g., 6.3 and 6.7 μ g. carotene and 1.9 and 2.1 μ g. vitamin A. The average tocopherol content, in μ g. per g., of the heart, lungs and testes of the group without supplement was, respectively, 34.2, 23.9 and 13.2, and of the group given the supplement 40.2, 32.5 and 18.6.

4785

ARNRICH, L. The effect of hypothyroidism on the metabolism of carotene in dogs. *J. Nutrition*, 1955, 56, 35-49. [Dept. Home Econ., Univ. California, Berkeley.]

Six purebred cocker spaniels were given a diet free from vitamin A until, at 3 months of age, liver biopsy showed them to have been depleted of their stores of the vitamin. They were then given 12.9 mg. carotene daily for 16 months. At the beginning of an 8-month experimental period which followed, liver biopsy was performed to estimate the vitamin A concentration in the liver and was repeated after 4 months. For the remaining 4 months thiouracil was given to 3 of the dogs as 0.74 per cent. of the diet. Vitamin A, carotene and cholesterol in the serum were estimated at regular intervals throughout the 8-month period.

When administration of carotene began and when the vitamin A concentration in the liver was, on the average, 10.3 $\mu\text{g. per g.}$, the average value for vitamin A in the serum was 108 $\mu\text{g. per 100 ml.}$ During the next few months it rose to an average of 300 $\mu\text{g. per 100 ml.}$ and continued so with little change. When thiouracil was given, the concentration of vitamin A in the serum rose in all 3 dogs, rapidly in one but more slowly in the other 2; at the end of the experiment the mean value was 881 for those given thiouracil and 333 for those not given it. In the serum of treated dogs small amounts of carotene were found; mean values for cholesterol were 551 and 188 mg. per 100 ml., respectively, for the treated and untreated dogs. Absorption of a single dose of carotene was reflected by a peak in the serum vitamin A concentration between 8 and 11 hr. after the dose; the average increase was 87 $\mu\text{g. per 100 ml.}$ in the untreated dogs and 128 in the treated. Before administration of thiouracil the livers of the untreated animals contained, on the average, 234 $\mu\text{g. per g.}$ those of the treated 218; at autopsy the average value for the untreated dogs was 378 $\mu\text{g. per g.}$ and for those treated 335 $\mu\text{g. per g.}$ Vitamin A was found in the urine of only one dog.

ALMQUIST, H. J. and MAURER, S. The effect of antibiotic, antioxidant, and fat on conversion of carotene to vitamin A in the chicken. *Arch. Biochem. Biophys.*, 1955, 55, 297-298. [The Grange Co., Modesto, Calif.]

Crossbred Indian River \times New Hampshire broiler chicks were given a diet containing only plant sources of vitamin A potency, generally as 5 per cent. of dehydrated alfalfa meal giving a total activity of about 11,000 I.U. per kg. diet. Carotene and vitamin A were estimated in the liver after the chicks had received the diet alone or with different supplements for 8 or 10 weeks.

When 55 mg. chlortetracycline was added per kg. diet, the average amount of vitamin A in the liver after 10 weeks was 115 I.U. per g. compared with 83 when no antibiotic was added. For carotene the average content also was higher with the

supplement than without, the respective values being 8.8 and 5.6 $\mu\text{g. per g.}$ Larger amounts of antibiotic did not raise the vitamin A value further, and actually lowered the carotene value. Inclusion of 250 mg. N, N'-diphenyl-p-phenylenediamine per kg. diet gave average vitamin A and carotene values per g. liver of 89 I.U. and 6.8 $\mu\text{g.}$, respectively. Addition of 14.3 g. rice bran oil per kg. diet raised the vitamin A and carotene values in the liver, the averages after 10 weeks on the diet being per g. 103 I.U. and 6.6 $\mu\text{g.}$, respectively. The amount of fat in the diet appeared, therefore, to be of importance in studies of carotene utilization by the chick. No consistent relation was found between the storage of vitamin A in the liver and bodyweight.—I. M. Sharman.

BIERI, J. G. Utilization of circulating carotenoids in the chick and rabbit. *Arch. Biochem. Biophys.*, 1955, 56, 90-96. [Dept. Biochem. Nutr., Univ. Texas Med. Branch, Galveston.]

Leghorn chicks were fed on a diet deficient in vitamin A. When deficiency signs appeared the birds were grouped and given β -carotene or cryptoxanthin

emulsified in water with Tween 40. Doses were given by mouth or intravenously into the leg. The birds were killed from 6 to 24 hr. later, and total carotenoids and vitamin A were estimated in the blood serum and liver. From 6 to 11 hr. after 90 μ g. carotene had been given intravenously the average values for vitamin A were 1.8 μ g. per g. fresh liver, and 27.2 μ g. per 100 ml. serum; vitamin A was not found in significant amounts in the kidneys. Carotene in the serum rose, on the average, to 971 μ g. per 100 ml. When the amount injected was from 80 to 120 μ g. carotene and the analyses were made 24 hr. later, the average value for the liver was 3.1 μ g. vitamin A per g., and for the serum 27.9 μ g. per 100 ml., a value resembling that after 6 hr.; liver carotenoid values averaged 12.2 μ g. per g. after from 6 to 11 hr. and 5.9 after 24 hr. When the birds were killed 10 hr. after having 90 μ g. carotene given by mouth the liver contained, on the average, 7.9 μ g. per g. Four New Hampshire chicks, also deficient in vitamin A, were injected with 400 μ g. cryptoxanthin and were killed 6 hr. later. Only traces of vitamin A were found in the liver and serum.

Rabbits deficient in vitamin A were injected in the ear vein with 600 μ g. carotene in 0.6 ml. aqueous solution. The animals were decapitated from 4½ to 24 hr. later and the serum, kidneys and liver were analysed for vitamin A. Similar rabbits given no injection showed no carotene or vitamin A in any of the tissues. In treated animals the value for vitamin A ranged from 21.2 to 33.6 μ g. per 100 ml. in serum, from 2.4 to 7.3 μ g. in the whole kidneys, and from 0 to 13.3 μ g. in the whole liver. In the rabbit the metabolism of carotene given intravenously resembled that in the rat although in the blood after 24 hr. carotene remained high in the rabbit but had disappeared completely in the rat.—I. M. Sharman.

VAVICH, M. G., STULL, J. W., RAICA, N. and KEMMERER, A. R. Effect of nonfat milk on the utilization of carotene and vitamin A. *Arch. Biochem. Biophys.*, 1955, 55, 310-314. [Dept. Agric. Biochem., Coll. Agric., Univ. Arizona, Tucson.]

Albino rats from 12 to 14 days old were given a diet deficient in vitamin A. When growth ceased they were divided into groups each of 10 or 12 animals and were given supplements of carotene or vitamin A as emulsions. The supplements were prepared from oily solutions of carotene or vitamin A by dilution with an equal weight of Tween 80, followed by partial emulsification with fresh non-fat milk or distilled water at 100° F., and homogenisation. Another preparation was made from powdered non-fat milk. After being given the

supplements for 12 days the rats were killed and vitamin A was estimated in the liver. When given 56 μ g. carotene daily the group receiving the supplement emulsified in fresh non-fat milk had, on the average, 63.5 μ g. vitamin A per liver, and those receiving the supplement emulsified in water only 41.2 μ g. Others given 60 μ g. carotene daily had 82.8 μ g. vitamin A in the liver when the supplement was emulsified with reconstituted non-fat milk and 67.3 μ g. when emulsified with water. With only 32 μ g. carotene daily there was no difference between the water and milk homogenates in their effect on the storage of vitamin A. When the supplements were of vitamin A there was not usually any significant difference between the effect of the water and milk homogenates, but when 52 μ g. vitamin A was given daily the average storage was lower, 123.2 μ g., when the supplement was emulsified with reconstituted non-fat milk, than the average of 156.6 μ g. when the supplement was given emulsified with water. In general the experiments showed the presence in milk of some constituent which exerted a favourable effect on carotene utilisation, though its nature was not revealed.—I. M. Sharman.

4794

JARL, F. and HELLSTRÖM, V. Utilization of carotene from hay and sugar beet top silage by dairy cows. *Kgl. Lantbrukshögsk. Ann.*, 1954, 21, 31-39. [Nat. Animal Exp. Stat., Uppsala.]

Two groups of Holstein cows were given rations containing, as sole source of carotene, hay or silage made from sugar beet tops. The experiment was repeated in 2 subsequent seasons. The carotene content of the hay and silage varied from year to year but the amount given was adjusted to supply equal amounts of carotene to each group. The milk was tested weekly for carotene and vitamin A.

More carotene and slightly more vitamin A were secreted in the milk of the group given hay than of the group given silage. Possible explanations of the difference are discussed.—V. H. Booth.

4795

FRANKLIN, M. C., McClymont, G. L., BRIGGS, P. K. and CAMPBELL, B. L. Maintenance rations for Merino sheep. 2. The performance of weaners fed daily and weekly on rations of wheat and wheaten chaff at maintenance levels and the effect thereon of vitamin A supplements. *Austral. J. Agric. Res.*, 1955, 6, 324-342. [Div. Animal Health Prod., C.S.I.R.O., McMaster Animal Health Lab., Sydney.]

For part 1, see Abstr. 3084, Vol. 22.

Groups of from 20 to 42 Merino weaners were given a ration providing 3.33 lb. starch equivalent per head weekly to maintain bodyweight at about 40 lb. Three rations, containing equal parts of

wheaten chaff and wheat, or 1 part of wheaten chaff and 9 of wheat, or wheat alone were provided. Deficiency of Ca was corrected by adding finely ground limestone and, for half the sheep, deficiency of vitamin A was corrected by an initial dose of 500,000 I.U. per head. Each ration was given to 2 groups, to one weekly and to the other daily. The trials lasted for 243 days. The average percentage death rate was 39.8 for those fed daily and 35.4 for those fed weekly. The surviving sheep in the groups fed daily maintained mean bodyweight and general condition as well as those fed weekly. Vitamin A in the plasma of those not given vitamin A fell to low values, ranging from 1.7 to 12.0 μg . per 100 ml., and the death rate was 63 per cent. Corresponding values for the animals given vitamin A were from 8.0 to 28.8 μg . per 100 ml. and 16.7 per cent. Post-mortem examination of the animals dying from deficiency of vitamin A showed no pathological signs other than those caused by anorexia and inanition. Bodyweight change and eventual loss were not affected by supplementing the ration of wheat alone with 0.5 per cent. sodium chloride. No significant difference in wool production was found in any of the groups given these simple cereal rations planned for drought, in these amounts, but significant increases were found in similar groups given the diets to appetite.—I. M. Sharman.

HØIE, J. and SANDVIK, Ø. Forsøk med tørrvitamin-preparater til kyllinger. [Experiments with dry vitamin preparations for chickens.] *Tidsskr. norske Landbruk*, 1955, 62, 47-58. [Landbrukshøgsk. Inst. Fjerde Pelsdyr.]

The experiments were designed to test the keeping qualities of 2 dry preparations of vitamins A and D in rations for chickens. They were mixtures of 94 per cent. maize meal with 6 per cent. of a molecular distillate, guaranteed to contain 1000 I.U. vitamin A and 100 I.U. vitamin D per g., or with 6 per cent. of a plant vitamin oil with the same guaranteed activity. They were compared with a medicinal cod liver oil providing about 770 I.U. vitamin A and 77 I.U. vitamin D per g. Three rations were used, one low in carotene and Ca, one with little carotene but normal amounts of Ca and P, and one high in carotene with little Ca. Each diet was given alone or with a supplement of 1.3 per cent. of medicinal cod liver oil, or 1 per cent. of a concentrate, to 12 groups of chickens from 5 to 8 weeks old. The supplements were mixed with the rations of cereal, legume, oil-cake, yeast and minerals at the beginning of the first 2 experiments and for the third the mixture was stored for 4 months.

There was no difference in the rate of growth of the chickens between the supplements, whether

used at once or stored for 4 months, in the generous amounts given. Chickens given the stored feed grew slightly less rapidly than the others, but the difference may have been due to seasonal change in rate of growth.—I. Leitch.

LIVINGSTON, A. L., BICKOFF, E. M. and THOMPSON, C. R. Effect of added animal fats and anti-oxidant on stability of xanthophyll concentrates in mixed feeds. *J. Agric. Food Chem.*, 1955, 3, 439-441. [W. Utilization Res. Branch, Agric. Res. Serv., U.S. Dept. Agric., Albany 10, Calif.]

Storage studies were made on 4 commercial xanthophyll concentrates, 2 made from dried alfalfa meal, 1 from lettuce meal and 1 from maize gluten meal. The stability of the carotenoids was low in one of the concentrates from alfalfa which had been prepared after saponification, perhaps because natural anti-oxidants had been removed. Specimens of the concentrates were treated with 6-ethoxy-1:2-dihydro-2:2:4-trimethylquinoline in 2 concentrations or with white tallow or with the anti-oxidant and white tallow. Treated and untreated concentrates were stored for 4 months at 25°C. as constituents of a series of broiler feeds. Both carotene and "xanthophyll" were estimated before and after storage.

Xanthophyll was more stable in the mixed feed than in the original concentrates. Both carotene and xanthophyll were more stable in material treated with anti-oxidant than in untreated material. The added fat also had a stabilising effect, probably by bringing natural anti-oxidants and carotenoids into more intimate contact. The effects of fat and anti-oxidant were additive.

The specimens described above were stored in containers which allowed access of air. The xanthophyll was completely stable in other specimens stored in closed containers.

HALVERSON, A. W. and HENDRICK, C. M. Effect of trace minerals and other dietary ingredients upon vitamin A stability in stored poultry diets. *Poultry Sci.*, 1955, 34, 355-360. [Dept. Biochem., Exp. Stat., S. Dakota State Coll., College Station.]

Three practical diets, differing in their cereal constituents, were supplemented with vitamin A

from cod liver oil, or a stabilised fish oil in dry fat, or a wax-coated preparation. Each diet was modified by the addition of meat scraps and limestone or by the further addition of Mn alone or with Fe, Cu and Co salts. One diet, a mash concentrate, included, in its modified forms, fishmeal and bonemeal. Samples in paper sacks were stored at 37° C. for 30 and 150 days. Loss after 30 days was in general small, but after 150 days it had increased to 50 per cent. or more. The replacement of one cereal by another, or the addition of meat scraps, limestone, fishmeal and bonemeal did not appreciably affect the stability of the vitamin A, nor did the further addition of Mn, but when Fe, Cu and Co also were present the loss was considerably increased, especially after 150 days' storage. The loss of vitamin A was greatest in the mash concentrate, which was higher in trace minerals than the other 2 diets. In all 3 diets, the stability of vitamin A in the wax-coated supplement was much greater than in the other two, the loss being only from 1/3 to 1/2 as much. The vitamin was equally stable in cod liver oil and stabilised fish oil.—E. M. Cruickshank.

- PATEL, H. S. and PATEL, B. M. Vitamin A potency of colostrum from Kankrej cows. *Indian J. Dairy Sci.*, 1955, 8, 14-18. [Inst. Agric., Anand.]

Samples of colostrum from 8 Kankrej cows and 1 Sindhi × Kankrej crossbred were drawn 4 hr. after parturition, and fat, carotene and vitamin A were estimated. Samples from subsequent milkings up to the eighth were similarly analysed. The yield of the first colostrum ranged from 5 to 18 lb., average 10.4, the percentage of fat from 0.5 to 9.2, average 3.25. The yield is 30 to 40 per cent. above that of some other milk breeds in India; the fat percentage is correspondingly lower. In the second milking the total yield dropped to 5.7 lb. and the fat percentage rose to 5.3. The yield gradually rose to 8.3 lb. at the eighth milking; the fat percentage varied irregularly between 4.5 and 5.5. The average carotene content of the colostrum was 45.7 µg. per g. fat, range 16.5 to 141.0, for the first milking and fell progressively to 7.3 at the eighth milking. The average vitamin A value was 285 I.U. per g. fat, range 175 to 612, for the first milking, and it also fell progressively to 55 at the eighth milking. The total secretions of carotene and vitamin A were 5305 µg. and 39,142 I.U. for the first milking and 1697 µg. and 12,227 I.U. for the eighth. The total carotene and vitamin A secreted in the first colostrum was therefore approximately 3 times that in the eighth milking. The first samples of colostrum were 12 times as rich in carotene and 10 times as rich in vitamin A as milk from normal herds.—I. M. Sharman.

VITAMIN D

4801

- LAPINA, A. A. Uproshchennyi biologicheskii metod opredeleniya vitamina D₂. [A simplified biological method for estimating vitamin D₂.] *Vop. Pitan.*, 1955, 14, No. 2, 18-21. [Inst. Vitaminol., Minist. Zdravookhran. SSSR, Moscow.]

In 2 series of experiments each with a large number of rats, the minimum prophylactic dose of vitamin D₂ was estimated from the number of animals with normal bones and the number with rickets for the different doses. It made little difference to the results whether the vitamin was administered daily or only twice in the course of a 15-day experiment.—D. W. Taylor.

4802

- BRUNE, H. Zur röntgenographischen Technik bei der biologischen Vitamin D-Bestimmung mit Ratten. [X-ray technique for estimating vitamin D biologically with rats.] *Ztschr. Tierernährung Futtermittelk.*, 1955, 10, 40-44. [Inst. Tierphysiol., Univ. Göttingen.]

The importance is stressed of ensuring that the rat's leg is always in the same position when radiography of the proximal end of the tibia is being used to assess antirachitic potency. Otherwise measurement of the width of the epiphyseal cartilage will not give consistent results. A method is described for securing constancy of position.

- ROSENBERG, H. R. The antirachitic activity of irradiated corbisterol. *Arch. Biochem. Biophys.*, 1955, 56, 256-258. [Stine Lab., E.I. du Pont de Nemours and Co., Inc., Newark, Del.]

At the request of its discoverer, Toyama (*J. Chem. Soc., Japan*, 1943, 64, 326), corbisterol was tested biologically with chicks and rats. Toyama isolated it from the bivalve mollusc *Corbicula leana*, and showed the presence in it of the 5:7-diene structure characteristic of provitamin D. The purity of the sample sent was about 57 per cent. It was saponified and the non-saponifiable fraction in ether was irradiated with ultraviolet light, a

N.A. and R., October 1955

sample of 7-dehydrocholesterol being exposed at the same time for comparison. Both irradiation products were dissolved in maize oil.

Tested on rats by the U.S.P. XIV method, corbisterol had the same antirachitic potency as the sample of vitamin D₃ prepared at the same time. Tested on chicks by the A.O.A.C. method (*Methods of Analysis*, 6th ed., 1945), the antirachitic potency of corbisterol was only about 4 per cent. of that of the sample of vitamin D₃. It is concluded that corbisterol probably belongs to the C₂₈ series of activated 7-dehydrosterols.

FESTENSTEIN, G. N. and MORTON, R. A. **Pro-vitamin D in animal tissues.** *Biochem. J.*, 1955, **60**, 22-25. [Dept. Biochem., Univ. Liverpool.]

It was previously demonstrated (Abst. 1842, Vol. 22) that reversible formation of 7-dehydrocholesterol from cholesterol occurred in the intestinal wall of the guineapig, and the existence of a sterol dehydrogenase was postulated. Animal tissues were investigated with a photo-electric spectrophotometer for the presence of 7-dehydrosteroid, defined as material showing the characteristic absorption of 7-dehydrocholesterol, ergosterol and other 5:7-dien-3-ol steroids. The tissues were extracted with ether, often after saponification, and the material was subjected to chromatography. The presence of 7-dehydrosteroid in the ovaries of mature frogs before hibernation was confirmed (Abst. 4688, Vol. 19), and it was found also in pig skin, pig intestine, horse stomach and intestine, and ox and sheep intestine.

It is considered probable that though the amount of 7-dehydrosteroid in the animal intestines examined was small, it was consistent with the widespread distribution of a special dehydrogenase of which the normal substrate is cholesterol, most probably of endogenous origin.—E. M. Hume.

4805

FESTENSTEIN, G. N. **The effect of ergosterol and ergocalciferol on the anaerobic glycolysis of rat-liver slices.** *Biochem. J.*, 1955, **59**, 605-609. [Dept. Physiol., Univ. Witwatersrand, Johannesburg.]

Rats weighing from 100 to 250 g. were maintained on a diet of, per cent., maizemeal 69, brewer's yeast 8, fat 8 and milk powder 15, with 6 ml. hake liver oil per lb. diet. The animals were killed after fasting for 16 hr., and slices were taken from the liver for measurement of anaerobic glycolysis in a Warburg flask. The incubation medium was bicarbonate Ringer solution containing 0.2 per cent. glucose. To dissolve the sterols, propylene glycol and Tween 80 could not be used since they inhibited glycolysis, but lecithin proved

satisfactory if results were restricted to the first hour. Concentration of ergosterol and ergocalciferol was measured with a Beckman spectrophotometer. Both substances caused inhibition of glycolysis by the liver slices, but ergosterol appeared to have a greater effect on male tissue and ergocalciferol on female. The rate of inhibition by ergosterol of male liver slices decreased with time, otherwise the rate of inhibition was constant. Spectrophotometric examination of the solutions after incubation showed increased absorption at 290 mμ., the significance of which was not determined.—E. M. Hume.

4806

MIGICOVSKY, B. B. and JAMIESON, J. W. S. **Calcium absorption and vitamin D.** *Canad. J. Biochem. Physiol.*, 1955, **33**, 202-208. [Div. Chem., Sci. Serv., Dept. Agric., Ottawa.]

Day-old chicks were given an A.O.A.C. rachitogenic diet. After 2 weeks vitamin D was included in the diet of half the chicks to give 1 "unit" per g. After another week all were given ⁴⁵Ca orally to supply 5 mg. Ca. The chicks were killed at intervals up to 6 hr. later, and blood and bone from the tibia were analysed for ⁴⁵Ca. The specific activity of the blood and bone rose much more rapidly and reached a much higher level when vitamin D had been given. When ⁴⁵Ca was given by intramuscular injection to chicks which had had a diet of Ca percentage ranging from 0.30 to 2.18, half of them having had vitamin D as before, the percentage of the ⁴⁵Ca dose found in the tibia did not differ significantly whether vitamin D had been given or not. It was, therefore, concluded that the percentage of an oral dose of ⁴⁵Ca which appeared in bone could be taken as a measure of an organism's capacity to absorb Ca.

Day-old chicks were reared as before to 3 weeks of age, half of them receiving vitamin D in the diet for the last 2 weeks. After 24 hours' fast, the dose of ⁴⁵Ca was given orally with doses of Ca ranging from 0.7 to 20 mg. The percentage of the ⁴⁵Ca dose found in the tibia fell with increasing dose of Ca, whether vitamin D had been given or not, but the percentage was always higher with vitamin D than without.

When the diet contained percentages of Ca ranging from 0.30 to 2.18, and the dose of ⁴⁵Ca was given orally, the percentage of the ⁴⁵Ca dose in the tibia decreased as the amount of Ca offered increased when vitamin D was given but not when it was not given. The last result is concluded to confirm the finding of Nicolaysen *et al.* (Title 797, Vol. 24), that there is an adaptation mechanism for dealing with a low Ca intake, which operates in presence of vitamin D but not in its absence.

It is suggested that "the action of vitamin D may be explained by a reaction of the vitamin or

a derivative thereof with calcium at the absorp-tion barrier".—E. M. Hume.

4807

VAN KESSEL, H. I. A. M. Invloed van grote doses vitamin D₂ en van vasten op de fosfaat-stofwisseling van de rat. [Effect of large amounts of vitamin D₂ and of fasting on phosphorus metabolism in the rat.] *Chem. Weekblad*, 1952, 48, 731-732. [Lab. Physiol. Chem., Rijksuniv. Utrecht.]

Three groups of 12 rats were normally fed to appetite, one group until 4 hr. before the study of P metabolism; a second was treated like the first but was given a single dose of 2 mg. vitamin D₂ by stomach tube 24 hr. before the study, and the third was fed up to 24 hr. before the study, from which time it fasted. ³²P, carrier-free [amount not stated] was injected into the abdominal cavity of 4 rats in each group 5, 10 or 20 min. before decapitation. Specific activity was measured of inorganic serum P, inorganic intracellular liver P, and phospholipin P of the liver.

The results are presented in graphs and interpreted to mean that fasting accelerates the transfer of inorganic serum P to the P of the intracellular space of the liver, and that vitamin D₂ accelerates the incorporation of inorganic intracellular liver P into the phospholipins of the liver.—I. Leitch.

4808

CRAWFORD, J. D., GRIBETZ, D. and TALBOT, N. B. (with TERRY, M., MACLACHLAN, E. A., VAN LOON, K. and MORRILL, M. F.) Mechanism of renal tubular phosphate reabsorption and the influence thereon of vitamin D in completely parathyroidectomized rats. *Amer. J. Physiol.*, 1955, 180, 156-162. [Dept. Paediat., Harvard Med. Sch., Boston, Mass.]

Parathyroid tissue was removed as completely as possible from male rats weighing from 150 to 400 g. A test for the completeness of the operation was made by loading them with phosphate and accepting for further experiment only those rats in which the serum inorganic P rose to 10 mg. per 100 ml. Rats thus selected were given daily for at least 4 days and sometimes for from 2 to 3 weeks 100, or 10,000 or 100,000 I.U. vitamin D₂. From 2 to 4 days before the beginning of the metabolic studies, rats in each of the 3 groups were given diets containing amounts of phosphate ranging from a trace to the maximum amount tolerable. Blood and urine samples were collected after comparable periods, and inorganic P and creatinine were estimated in them; the rate of glomerular filtration was estimated from the endogenous creatinine clearance.

With each amount of vitamin D there was a general tendency for the amount of P in the urine

to increase as the amount of P filtered by the glomeruli increased; the amount of P in the urine for a given amount of P filtered by the glomeruli tended to be greater, the greater the amount of vitamin D previously given.

The object of the study was to ascertain "whether under conditions of constant parathyroid and vitamin D status, there is a renal tubular transfer maximum for inorganic phosphate or, alternatively, a tendency for the tubules to reabsorb a constant fraction of the phosphate filtered by the glomeruli". The results fitted the latter, not the former hypothesis.—E. M. Hume.

ENGEL, C. Der Vitamin-D-Gehalt von mit U.V.-Licht bestrahlter Milch. [Vitamin D content of milk irradiated with ultraviolet light.] *Milchwissenschaft*, 1954, 9, 378-379; *Centraal Inst. Voedingsonderzoek T.M.O., Utrecht, Publ.* No. 192. English and Spanish summaries.

Irradiated condensed milk was prepared in Bremen at the *Milchabsatzgenossenschaft* under the supervision of the *Landesgesundheitsverwaltung*, and was tested at Utrecht in the Pharmacological Laboratory of the *Rijksinstituut voor de Volksgezondheid* and in the Hygiene Laboratory of the University.

In tests with rats at the Pharmacological Laboratory, ether-extracted skimmed milk powder was given to negative control animals to balance any antirachitic effect of the constituents of the condensed milk other than vitamin D. In the Hygiene Laboratory the doses of milk given were considered too small for such a procedure to be necessary. The experiments at the Hygiene Laboratory are set out. Groups of 12 rats received 1 or 2 ml. of the condensed milk or one of 5 doses of the International Standard for vitamin

D, daily for 10 days, after which X-ray photographs were taken. The vitamin D content found was 450 I.U. per kg.; the value found at the Pharmacological Laboratory was 400.

Another sample of irradiated condensed milk, brand Sonnenquell, was bought in a retail shop in Bremen and tested on chicks at the *Rijksinstituut voor Pluimveeteelt* in Beekbergen. The value found was 527 ± 107 I.U. per kg.—E. M. Hume.

VITAMIN E

4814

GREEN, J., MARCINKIEWICZ, S. and WATT, P. R. The determination of tocopherols by paper chromatography. *J. Sci. Food Agric.*, 1955, 6, 274-282. [Walton Oaks Exp. Stat., Vitamins, Ltd., Tadworth, Surrey.]

Individual tocopherols were separated by a one-dimensional separation on paper impregnated with zinc carbonate with or without a second-dimensional partition on paraffin-coated paper. The papers were prepared by being immersed for a short time in a solution of zinc ammine carbonate, dried at room temperature and heated to between 95° and 100° C. to decompose the complex. The oil or fat was saponified and, as a rule, was applied to the chromatograms directly. It was sometimes necessary to pass the unsaponifiable matter through Floridin earth to remove sterols. Ascending chromatography was used with cyclohexane as developing solvent. R_F values of the tocopherols were for α -0.66, β -0.43, γ -0.43, and δ -0.20, and for β -carotene and vitamin A alcohol 0.71 and 0.35. Two-dimensional chromatography was achieved by running the tocopherols on the side of a square sheet of zinc-carbonate paper; after development in cyclohexane the unused paper was treated with a solution of liquid paraffin in light petroleum, and development was with 75 per cent. ethanol. Only β - and γ -tocopherols remained unseparated by the method. Recovery of 98 per cent. was obtained when pure tocopherols were applied to the paper.

When the unsaponifiable fraction of coarse bran was chromatographed a new spot appeared which ran with α -tocopherol in the first dimension and with β -tocopherol in the second dimension. The spot was considered to be due to 5:7-dimethyl-tocol, to which the prefix ζ has been given. The substance did not couple with diazotised o-dianisidine and did not form a nitroso-derivative. The new ζ -tocopherol was found to be the main form in barley oil. δ -Tocopherol, previously known

only in soya bean oil, was found to occur in oat and mustard seed oil.—R. J. Ward.

LA GRUTTA, G. and CILENTO, A. Metabolismo glicidico e vitamina E. [Carbohydrate metabolism and vitamin E.] 2. Contenuto in glicogeno dei muscoli scheletrici, del fegato e del cuore di ratti normali e diabetici per allosana trattati con vitamina E. [2. Glycogen content of the skeletal muscle, liver and heart of normal rats, and rats made diabetic with alloxan, treated with vitamin E.] 3. Fosforo ematico inorganico e sue modificazioni in rapporto alla somministrazione di vitamina E in conigli normali e diabetici. [3. Inorganic blood phosphorus and its modifications in

relation to the administration of vitamin E to normal and diabetic rabbits.] *Bol. Soc. ital. Biol. sper.*, 1953, 29, 1573-1575; 1575-1577. [Ist. Fisiol., Univ. Palermo.]

For Part 1 see Abst. 2978, Title 2979, Vol. 24.

2. Glycogen was estimated in the liver, skeletal muscles and heart of male rats weighing about 169 g., maintained on a normal diet. Groups of from 5 to 8 were given no treatment, or a subcutaneous injection of from 3 to 6 mg. vitamin E daily for 7 days without other treatment; 3 other groups were rendered diabetic with alloxan and were given the injections of vitamin E for a week from the onset of diabetes, or for a week before the giving of alloxan till the end of the experiment, or not at all. No significant change in the glycogen values attributable to vitamin E was found except that the glycogen content of the heart muscle was greater in the diabetic rats when vitamin E was given.

3. Inorganic P was estimated in the blood of 7 male rabbits, weighing about 2 kg., before and 60 and 120 min. after intramuscular injection of from 100 to 200 mg. α -tocopherol, given alone or with glucose, and after administration of glucose alone or with insulin. After 30 days' pause the same rabbits were made diabetic with alloxan, and the tests were repeated. No evidence of an effective action of vitamin E on carbohydrate metabolism was obtained from the results of measuring the serum inorganic P. (See also Title 3455, Vol. 25.)

In the course of a general article and review, the results of 2 experiments are reported.

Blood sugar was estimated in rabbits weighing from 2 to 3 kg., injected subcutaneously after 24 hours' fast with 0.1 mg. per kg. bodyweight of an adrenaline preparation, Tonogen. The rabbits were then given 50 mg. *dl*- α -tocopheryl acetate daily for 10 days. The blood sugar curve in response to adrenaline rose much higher after tocopherol treatment than before it, from which it is concluded that vitamin E protects the reserves of glycogen in the liver.

Of 2 groups of rats weighing from 100 to 150 g., one was given 25 mg. *dl*- α -tocopheryl acetate daily for a preliminary period. Rats from both groups were then killed after fasting for 3, 6, 9, 24 and 48 hr., and glycogen was estimated in the liver. The fall was much more rapid in the rats not previously given tocopheryl acetate.

Muscle was collected from young rabbits which had been rendered dystrophic with a diet which had been treated with ferric chloride. Some rabbits having the same diet were given tocopherol. The proteolytic activity of homogenates and extracts of the muscles from the dystrophic and normal animals was compared by incubating them with denatured haemoglobin, with or without the presence of the ferrous ion, and by recording the increase in absorption at 280 m μ . after the precipitation of residual protein with trichloroacetic acid. The proteolytic activity was always greater in the preparations from dystrophic muscles than from normal muscles. The same difference was found whether the ferrous ion was present or not.

KING, J. T., LEE, Y. C. P. and VISSCHER, M. B. Relationship between vitamin E and dietary minerals in mouse "paralysis". *Proc. Soc. Exp. Biol. Med.*, 1955, 88, 406-409. [Dept. Physiol., Univ. Minnesota, Minneapolis.]

Five groups of C₃H male mice were restricted when about 3 weeks old to a diet containing casein, glucose, lard, dried yeast, dried alfalfa, and cod liver oil, with one of 3 different salt mixtures. Three of the groups received wheat germ as a source of vitamin E, and 2 did not. When the

N.A. and R., October 1955

salt mixture contained ferric phosphate as its source of iron, and no trace element except iodine was included, paralysis appeared after 6 months in all the animals which did not receive wheat germ, but not within 12 months in those which did. When ferrous sulphate was substituted for ferric phosphate, and manganese, zinc, copper and cobalt were included in the salt mixture, there was no paralysis either with or without wheat germ. When ferrous sulphate was substituted for ferric phosphate, but no trace element except iodine was given, the mice became paralysed after 6 months, even with wheat germ in the diet.

SINGSEN, E. P., BUNNELL, R. H., MATTERSON, L. D., KOZEFF, A. and JUNGHERR, E. L. Studies on encephalomalacia in the chick. 2. The protective action of diphenyl-*p*-phenylenediamine against encephalomalacia. *Poultry Sci.*, 1955, 34, 262-271. [Dept. Poultry Sci., Storrs Agric. Exp. Stat., Univ. Connecticut.]

For other parts see Abst. 4361, Vol. 24; Titles 1890, 3122, Vol. 25.

Chicks deprived of vitamin E were given for 28 days a diet low in the vitamin or a normal diet, both of them supplemented with amounts of fish oil up to 8 per cent., alone or with the further addition of vitamin E up to 16 I.U. per lb. On the deficient diet, which contained less than 3 I.U. vitamin E per lb., the chicks grew normally and had no encephalomalacia although the blood contained only 0.10 mg. per cent. of tocopherol. The inclusion of oil in both diets reduced blood tocopherol and greatly increased mortality and the incidence of encephalomalacia, the effect being greatest with the diet low in vitamin E. Chicks given the normal diet with from 2 to 8 per cent. of added oil frequently showed signs of encephalomalacia though the blood tocopherol was above 0.10 mg. per cent. The results showed that between 7 and 11 I.U. vitamin E per lb. feed was sufficient to prevent the disease in field conditions.

When the ration was low in vitamin E and contained 2 per cent. of oil, 0.025 per cent. of diphenyl-*p*-phenylenediamine completely prevented encephalomalacia; 0.0125 per cent. was not entirely effective, but would probably be so with practical rations. The results suggest that vitamin E prevents encephalomalacia by acting as a biological anti-oxidant and that diphenyl-*p*-phenylenediamine acts in the same way and exerts its main protective action within the body, probably in the

intestinal tract, rather than by protecting vitamin E in the food.—E. M. Cruickshank.

BIAVATI, F. Osservazioni di sterilità nel ratto albino alimentato con dieta prevalentemente maidica. [Sterility in white rats fed on a diet chiefly of maize.] *Bol. Soc. ital. Biol. sper.*, 1953, 29, 1407-1409. [Ist. Fisiol., Univ. Bologna.]

With a diet of, per cent., maize meal 60, crude casein 15, whole milk powder 12, linseed meal 10, cod liver oil 1, CaCO_3 1, and iron lactate 1, with brewer's yeast 5 per cent. of the whole, and twice a week greenstuff and fresh liver, male and female rats left together failed to produce young, and the male gonads were found to be atrophic.

The same females were then fed on the same diet or the same diet with oatmeal instead of maize meal, or a diet of Randoin with only 15 per cent. maize meal, a mixture of cereals, 5 per cent. wheat germ and no cod liver oil. After a month they were mated with fertile males and all became pregnant. The group of 5 with 60 per cent. maize meal produced dead young or failed to rear them; of 6 in the group with oatmeal, 2 failed to rear their young, and of 5 in the group with the diet of Randoin, 2 failed to rear their young.

ATKINSON, R. L., FERGUSON, T. M., QUISENBERRY, J. H. and COUCH, J. R. Vitamin E and reproduction in turkeys. *J. Nutrition*, 1955, 55, 387-397. [Dept. Biochem., Texas Agric. and Mech. Coll. System, College Station.]

Small White turkey hens in 8 groups were given a diet with all-vegetable protein supplemented with minerals and vitamins except vitamin E. Each group of females was mated with a male of the same breed. Groups 1, 3, 5 and 7 were given the basal diet without supplement or with 5 per cent. condensed fish solubles or 3 per cent. dried whey or both. Groups 2, 4, 6 and 8 were given the same 4 diets with addition of 20 mg. α -tocopherol acetate per lb. After 9 weeks the tocopherol supplement was withdrawn from groups 2, 4, 6 and 8 and given to groups 1, 3, 5 and 7. Records were kept of egg production, number of eggs set, fertility and hatching capacity, and the tocopherol content of the egg yolks was estimated.

Supplements other than tocopherol had no effect on egg production, fertility or hatching capacity. The hatching capacity was higher by about 36 per cent. in the group given tocopherol in the first 9 weeks than in those not given it. The hatching capacity of eggs from the hens without tocopherol increased by 17 per cent. when tocopherol was given; it fell by 9 per cent. after tocopherol was withdrawn from those that had previously received it. Tocopherol had no effect on egg production or fertility.

There were 309 dead embryos in 652 fertile eggs during the first 9-week period from hens not receiving tocopherol but only 83 in 708 fertile eggs from those given tocopherol. In the 9th week, the average tocopherol content per yolk of the eggs from the hens receiving tocopherol was 838 μg . and from those not receiving it 200 μg . In the 17th week, after the diets had been reversed, the values were 215 and 747 μg . per yolk.

4834

SAFFORD, J. W. and SWINGLE, K. F. Plasma and milk tocopherol levels of cows compared with the plasma tocopherol levels of their foster calves. *Amer. J. Vet. Res.*, 1955, 16, 64-68. [Montana Vet. Res. Lab., Bozeman.]

Three cows from ranches in Western Montana where muscular dystrophy occurred and whose calves had died from it were used to rear 3 normal male Jersey calves. Hay of specified quality was the only food of the cows for about 2 months after the adoption of the calves. Tocopherol was estimated weekly in the plasma of each cow and calf and daily in the milk from each cow. In the blood of the calves average values were 78.6, 37.4, and 21.4 μg . per 100 ml. Despite such low values, especially for the last 2, no clinical sign of muscular dystrophy was seen. Electrocardiograms were normal. The average values in the milk for the corresponding cows were 41.7, 26.8 and 42.5 μg . per 100 ml., and in the plasma 252, 244 and 231 μg . per 100 ml. The ratios of the tocopherol values in the cow's plasma, cow's milk and calf's plasma were, for the first cow and calf approximately 7:1:2, for the second 9:1:1.4 and for the third 11:2:1. No correlation was found between the value in the calf's plasma and in the ingested milk. Towards the end of the experiment the cows with their foster calves were allowed out on pasture. After 19 days the tocopherol values for both cows and calves rose to comparatively high levels in the plasma, but not in the milk of the cows.—I. M. Sharman.

4835

ANGLIN, C., MAHON, J. H. and CHAPMAN, R. A. Tocopherol content of Canadian butterfat and its use in detecting adulteration. *J. Dairy Sci.*, N.A. and R., October 1955

1955, 38, 333-339. [Dept. Nat. Health Welfare, Food and Drug Labs., Ottawa, Ont.]

Samples of butter were collected at monthly intervals between June 1953 and May 1954 from 29 manufacturers in 8 different provinces of Canada, and analysed for their tocopherol content. The average tocopherol content for the months, beginning with June, were in p.p.m., 34, 40, 42, 42, 42, 31, 27, 21, 19, 19, 21 and 26. The range was from 10 to 50 and the average for all the samples was 31. The factories supplying the butter obtained their milk from large numbers of cows, from 28,000 to 56,000, and it is, therefore, considered that the findings are representative of butterfat produced commercially in Canada. Examination of confidence limits showed that, for butterfat produced between July and October, 95 per cent. of unadulterated samples should have a tocopherol content below 49, 99 per cent. below 52 and 99-95 per cent. below 57 p.p.m. Of that produced from January to April, on the other hand, 95 per cent. of samples, should have below 27, 99 per cent. below 30 and 99-95 per cent. below 35 p.p.m. The value is emphasised of estimating tocopherol for detecting adulteration of butterfat with small amounts of vegetable fats. The method cannot be used to detect additions of coconut oil.—I. M. Sharman.

4836

RUCCIA, D. Ulteriori indagini sull'eventuale presenza di vitamina E nell'olio di oliva. Ricerche su ratti adulti a dieta priva di tocoferoli, accoppiati tra loro. [Further investigation of the possible presence of vitamin E in olive oil. Experiments with adult rats deprived of tocopherols and mated with one another.] Ricerche su ratti adulti a dieta priva di tocoferoli, accoppiati con ratti adulti normali. [Experiments with adult rats deprived of tocopherols and mated with normal adult rats.] *Bol. Soc. ital. Biol. sper.*, 1953, 29, 1601-1604; 1604-1607. [Ist. Fisiol., Univ. Bari.]

Four pairs of rats weighing about 140 g. were maintained on a diet deficient in vitamin E, with daily additions of 2 and later of 3 or 4 g. olive oil of varying degrees of refinement. No better evidence for the presence of vitamin E in olive oil was

obtained than in previous experiments of the same type (Abst. 2984, Vol. 24).

When males or females receiving the same diets as in the preceding experiment were mated with normal females or males, no conclusive evidence was obtained, and it is concluded that if vitamin E is present in olive oil the amount is not sufficient to be demonstrated in such a biological test.

LUCKMANN, F. H. and MELNICK, D. Tocopherol retention in oils aerated in glass and iron tubes. *J. Amer. Oil Chem. Soc.*, 1955, 32, 175-176. [Res. Labs., Best Foods, Inc., Bayonne, N.J.]

When hydrogenated soya bean oil was aerated in glass tubes the tocopherol content fell from an initial value of 0.087 per cent. to 0.019 per cent. after 20 hr. The addition of 2.0 p.p.m. Fe as iron stearate caused a fall to 0.011 per cent. after 20 hr. The addition of 0.08 per cent. isopropyl citrate esters retarded the loss of tocopherol in the oil with or without added iron. When the oil was aerated in iron tubes, its tocopherol content fell from 0.087 per cent. to 0.010 per cent. after 20 hr. With isopropyl citrate esters the fall was only to 0.033 per cent.—R. J. Ward.

4838

KOHLER, G. O., BEIER, E. and BOLZE, C. C. The stability of carotene and vitamin E in dehydrated forage crops. *Poultry Sci.*, 1955, 34, 468-471. [Cerophyll Labs., Inc., Kansas City, Mo.]

Dehydrated cereal grass which had been stored for 16 months at — 15° F. was thoroughly mixed and samples were stored in paper bags at 15°, 38°, 77°, 100° and 140° F.; other samples were stored in bottles under N. Carotene, vitamin E and moisture were estimated initially and at fortnightly intervals. The rate of loss of carotene and vitamin E followed the pattern of first order reactions. At 77° F. and above the loss of carotene and vitamin E was significant except in the gas-packed samples, in which the rate of loss of both constituents was negligible. A rise of 10° C. produced a percentage increase in the rate of loss of carotene of 75 ± 12 and of vitamin E of 53 ± 14 .

FROST, D. V. and SPRUTH, H. C. Control of haemorrhagic condition in chickens with menadione sodium bisulfite. *Poultry Sci.*, 1955, 34, 56-64. [Abbott Labs., N. Chicago, Ill.]

Vol. 25, No. 4

The successful control with menadione sodium bisulphite of haemorrhagic conditions occurring in large poultry flocks in the field is described. In laboratory tests on chicks given for 4 weeks a diet low in vitamin K, 0.05 per cent. arsenic acid failed to alter the blood clotting time; menadione

sodium bisulphite, from 90 to 180 mg. per ton diet, effectively reduced it. In chicks given a diet low in vitamin K and containing 0.1 per cent. sulphathiazine, the requirement for vitamin K was greatly increased, and in those conditions menadione sodium bisulphite was at least 4 times as effective as menadione for supplying vitamin K activity.

TRIBE, D. E. and GORDON, J. G. Choice of diet by rats. 5. Choice of diets containing various members of the vitamin B complex. *Brit. J. Nutrition*, 1955, 9, 200-202. [Rowett Res. Inst., Bucksburn, Aberdeenshire.]

See Abst. 373, Vol. 24.

Three comparable groups of rats were given a diet lacking in the vitamin B complex, or restricted or unrestricted amounts of the same diet with addition of pantothenate, nicotinic acid, inositol and *p*-aminobenzoic acid for a preliminary period. They were then offered for 15 days a different choice every day between pairs of diets including the one without B vitamins and a diet containing vitamin B₁ or the same with pyridoxine, or the same as the last with riboflavin, or the same as the last with pantothenate and nicotinic acid, or the same as the last with *i*-inositol and *p*-aminobenzoic acid. The rats which had been completely deprived of B vitamins showed a definite preference for diets

N.A. and R., October 1955

containing vitamin B₁ and riboflavin; those partly deprived showed a similar but less marked preference.—A. M. Copping.

4846

TIPTON, S. R., WELDEN, F. and WEISS, A. K. Effect of riboflavin or thiamin deficiency on the response of liver and kidney adenosine-triphosphatase and D-amino acid oxidase to thyroid and adrenal alterations in rats. *Amer. J. Physiol.*, 1955, 180, 321-324. [Dept. Zool. Entomol., Univ. Tennessee, Knoxville.]

Adenosine triphosphatase activity was measured by the method of DuBois and Potter (Abst. 3117, Vol. 13) and D-amino-oxidase by that of Axelrod, Sober and Elvehjem (Abst. 2530, Vol. 10) in liver and kidney from rats having a complete, purified diet or a diet lacking vitamin B₁ or riboflavin or the whole vitamin B complex. On a complete diet both phosphatase and oxidase activity in the liver were increased in rats receiving thyroxine or thyroid gland powder. The kidney enzymes were not affected. Lack of vitamin B₁ or of the whole vitamin B complex did not affect phosphatase activity or its response to thyroid hormone. Lack of riboflavin produced an increase in phosphatase activity of the liver and a decrease in oxidase of both liver and kidney. Thyroid hormone had no effect on the enzyme activities of the kidney in riboflavin deficiency. Adrenalectomy had little or no effect on liver phosphatase activity, but adrenal cortical extract decreased liver phosphatase in rats on a normal diet.

LAMANNA, A. and TAVIANI, L. Influenza dell'acido folico, dell'acido pantotenico e della vitamina B₆ sulla produzione di anticorpi agglutinanti. [Effect of folic acid, pantothenic acid and vitamin B₆ on the production of agglutinating antibodies.] Influenza della vitamina B₆, dell'acido folico e dell'acido pantotenico sulla fagocitosi. [Effect of vitamin B₆, folic acid and pantothenic acid on phagocytosis.] *Acta vitaminol.*, 1955, 9, 57-60; 61-63. [Lab. Direzione Med. Centrale, Lepetit S.p.A., Milan.] French, English, German and Spanish summaries.

Five groups of 12 rats, weighing about 300 g. and maintained on a complete diet, were given by subcutaneous injection daily for 30 days, per kg. bodyweight, 0.6 mg. folic acid or 3 mg. Ca pantothenate or 0.8 mg. vitamin B₆ or all three or no supplement. After 15 days all were given on alternate days 3 intraperitoneal injections of a killed vaccine of *Salmonella typhi* H 901. Seven, 15, 30 and 45 days later the agglutinating titre of the rats' blood was determined, but no difference referable to the vitamins given was found.

Vol. 25, No. 4

Leucocytes from rat's peritoneal exudate were incubated with cells of *Staphylococcus aureus* 131 in presence of pyridoxine hydrochloride, Ca pantothenate or folic acid or no addition. The number of leucocytes containing bacteria were counted. Pantothenate slightly depressed phagocytosis but otherwise there was no effect.

Fifty male rats weighing about 250 g. were treated for 15 days with the same 3 vitamins, separately or together or not at all. They were then injected intraperitoneally with *Staph. aureus* 131; 3 hr. later peritoneal exudate was removed, and the degree of phagocytosis by the leucocytes in it was estimated as before. There was no effect of the vitamins on phagocytosis except a small inhibitory one by pyridoxine. [Tables 1, 2 and 3 appeared subsequently, pp. 128-129.]

PRUZANSKY, J. and AXELROD, A. E. Effect of B-complex deficiencies on rat serum complement. *Proc. Soc. Exp. Biol. Med.*, 1955, 88, 179-181. [Inst. Pathol., W. Reserve Univ., Cleveland, Ohio.]

Serum complement was estimated with sheep's red cells in blood from rats deprived for 6 or 8 weeks of vitamin B₆, riboflavin, biotin or pteroyl-glutamic acid. Deprivation of vitamin B₆ or riboflavin lowered the serum complement value, but the effect appeared to be connected with the low food intake, since similar results were obtained in non-deprived rats, pair-fed with those deprived of riboflavin. The rate of regeneration of serum complement in rats deprived of vitamin B₆ and riboflavin was similar to that in "non-deprived" animals.—A. M. Copping.

KUPKA, E. and NEUHOLD, K. Über die Wirkung einiger Vitamin-B-Faktoren auf die experimentelle Diphtherie-Toxikose des Goldhamsters. [Action of certain vitamin B factors on experimental diphtheria toxicosis in the golden hamster.] *Ztschr. Vitamin-, Hormon- Fermentforsch.*, 1954, 6, 406-421. [Zool. Inst., Univ. Graz.] English and French summaries.

Studies were made with about 600 golden hamsters on the effect of the vitamin B complex on the response to lethal doses of diphtheria toxin. Preliminary tests with commercial preparations suggested that the vitamin B complex gave no protection, but administration of vitamin B₁ or

sodium bisulphite, from 90 to 180 mg. per ton diet, effectively reduced it. In chicks given a diet low in vitamin K and containing 0.1 per cent. sulphathiazine, the requirement for vitamin K was greatly increased, and in those conditions menadione sodium bisulphite was at least 4 times as effective as menadione for supplying vitamin K activity.

ARNON, D. I., WHATLEY, F. R. and ALLEN, M. B. Vitamin K as a cofactor of photosynthetic phosphorylation. *Biochim. biophys. Acta*, 1955, 16, 607-608. [Dept. Plant Nutrit., Univ. California, Berkeley.]

Menadione, vitamin K₃ and phthiocol and some other substituted naphthoquinones were found to act as co-factors in photosynthetic phosphorylation under anaerobic conditions in the presence of magnesium and ascorbate. Dicoumarol and other derivatives which inhibited vitamin K activity in blood clotting inhibited its action also in the phosphorylation system. Flavin mononucleotide enhanced the effect of low concentrations of vitamin K in phosphorylating processes. Possible systems of energy transfer in photosynthetic phosphorylation systems are discussed.—A. M. Copping.

GIACALONE, O. and MONACO, P. Influenze delle vitamine B₆, PP, B₁₂, sui processi ricostruttivi nella rialimentazione dopo digiuno. [Influence of vitamins B₆, PP and B₁₂ on the processes of reconstruction during refeeding after a fast.] *Bol. Soc. ital. Biol. sper.*, 1953, 29, 1570-1572. [Ist. Fisiol., Univ. Palermo.]

With the same technique as before (Abst. 2995, Vol. 24), groups of 5 rats of mean weight 170 g., which had been made to lose about 18 per cent. of bodyweight by semi-starvation, were fed to appetite on a diet of rice starch, casein, butter, salts and vitamins A, B, C, D, E and PP and riboflavin, with addition daily of 2 mg. vitamin B₆ (Benadon Roche) or 10 mg. vitamin PP (Benicot Roche), or 8 µg. vitamin B₁₂ (Rubramin Squibb), or no addition. Recovery of weight was no more rapid and food utilisation no better with any of the supplements than without them.

TRIBE, D. E. and GORDON, J. G. Choice of diet by rats. 5. Choice of diets containing various members of the vitamin B complex. *Brit. J. Nutrition*, 1955, 9, 200-202. [Rowett Res. Inst., Bucksburn, Aberdeenshire.]

See Abst. 373, Vol. 24.

Three comparable groups of rats were given a diet lacking in the vitamin B complex, or restricted or unrestricted amounts of the same diet with addition of pantothenate, nicotinic acid, inositol and *p*-aminobenzoic acid for a preliminary period. They were then offered for 15 days a different choice every day between pairs of diets including the one without B vitamins and a diet containing vitamin B₁ or the same with pyridoxine, or the same as the last with riboflavin, or the same as the last with pantothenate and nicotinic acid, or the same as the last with *l*-inositol and *p*-aminobenzoic acid. The rats which had been completely deprived of B vitamins showed a definite preference for diets

N.A. and R., October 1955

containing vitamin B₁ and riboflavin; those partly deprived showed a similar but less marked preference.—A. M. Copping.

TIPTON, S. R., WELDEN, F. and WEISS, A. K. **Effect of riboflavin or thiamin deficiency on the response of liver and kidney adenosine-triphosphatase and D-amino acid oxidase to thyroid and adrenal alterations in rats.** *Amer. J. Physiol.*, 1955, **180**, 321-324. [Dept. Zool. Entomol., Univ. Tennessee, Knoxville.]

Adenosine triphosphatase activity was measured by the method of DuBois and Potter (Abst. 3117, Vol. 13) and D-amino-oxidase by that of Axelrod, Sober and Elvehjem (Abst. 2530, Vol. 10) in liver and kidney from rats having a complete, purified diet or a diet lacking vitamin B₁ or riboflavin or the whole vitamin B complex. On a complete diet both phosphatase and oxidase activity in the liver were increased in rats receiving thyroxine or thyroid gland powder. The kidney enzymes were not affected. Lack of vitamin B₁ or of the whole vitamin B complex did not affect phosphatase activity or its response to thyroid hormone. Lack of riboflavin produced an increase in phosphatase activity of the liver and a decrease in oxidase of both liver and kidney. Thyroid hormone had no effect on the enzyme activities of the kidney in riboflavin deficiency. Adrenalectomy had little or no effect on liver phosphatase activity, but adrenal cortical extract decreased liver phosphatase in rats on a normal diet.

RAMASARMA, G. B., SHENOY, K. G. and PINTO, P. V. G. Vitamin and essential amino acid content of a domestic proteolysed liver. *J. Indian Med. Assoc.*, 1955, **24**, 575-578. [Res. and Control Div., Raptakos, Brett and Co., Ltd., Bombay.]

A new method for preparing a proteolysed liver product is described. Sixty kg. minced liver and 6 kg. minced pancreas were heated to 53° C. for 3 hr. in 180 litres distilled water. The mixture was then heated at 90° C. for ½ hr. to inactivate enzymes and coagulate the proteins. It was then passed through a filter press and the clear filtrate was concentrated to a syrupy consistency under reduced pressure.

Except for phenylalanine and arginine the content of essential amino-acids was similar to that obtained from beef liver after digestion with papain. The content of B vitamins, estimated microbiologically, was, per g. dry matter, vitamin B₁₂ 8.3 µg., citrovorum factor 9.1 µg., folic acid 10.3 µg., vitamin B₁ hydrochloride 11.8 µg., riboflavin 0.12 mg., nicotinic acid 0.74 mg., vitamin B₆ 20.1 µg., calcium pantothenate 0.32 mg., biotin 7.63 µg. These values were again similar to those found after papain digestion of beef liver.

The therapeutic value of proteolysed liver in the treatment of anaemia is discussed.—J. S. Thomson.

CONRAD, H. R. and HIBBS, J. W. Thiamine and riboflavin in various fractions of rumen contents of young calves. *J. Dairy Sci.*, 1955, **38**, 548. [Ohio Agric. Exp. Stat.]

In young calves analysis of total rumen contents, strained and centrifuged fractions and residues showed that rumen bacteria are a rich source of vitamin B₁ and riboflavin, which are bound in the bacterial cells. Rumen protozoa were rich in riboflavin but their vitamin B₁ content was no higher than that of the feed.—A. M. Copping.

4853

KOTSCHIEVAR, L. H. B-Vitamin retention in frozen meat. *J. Amer. Dietetic Assoc.*, 1955, **31**, 589-596. [Montana State Univ., Missoula.]

The effect of freezing, frozen storage, thawing, and, cooking with or without thawing, on the vitamin B₁, riboflavin and nicotinic acid content of liver was studied. When liver was frozen for 60 days, there was, in general, substantial loss of vitamin B₁ and riboflavin and some gain in nicotinic acid. In liver cooked in the frozen state,

slightly more vitamin B₁ and riboflavin and less nicotinic acid were retained than in liver cooked after thawing.

The quantity and vitamin content of the drip from thawing liver and from some meat cuts are tabulated. The quantity of drip was greater from liver and beefsteak than from other cuts of beef or from cuts of pork and lamb. The vitamin content of the drip was similar to that of the source of the drip before freezing.—F. C. Aitken.

4854

McCLYMONT, G. L. and DUNCAN, D. C. Studies on nutrition of poultry. 5. Comparative value of synthetic riboflavin and natural vitamin B complex rich feeds for supplementing wheat-meal rations for hatchability.

McDONALD, M. W. and McCLYMONT, G. L. 6. The effect of a simplified breeding ration on hatchability, and growth and viability of chickens. *Austral. Vet. J.*, 1955, **31**, 91-92; 93-97. [Nutrit. Res. Lab., Vet. Res. Stat., Glenfield.]

For earlier parts see Absts 5225, Vol. 17; 363, Vol. 18; 2522, Vol. 23; 4542, Vol. 24.

5. Three groups of 10 hens, kept in pens in which the litter was changed every week, were given to appetite a basal ration of meatmeal 10, NaCl 0.5, and ground wheat 89.5 parts with supplements of manganese sulphate and vitamins A and D₃, and with 3 p.p.m. of riboflavin. After a preliminary period of 2 months, all eggs laid during the next 3 months were incubated. In that time egg production was 57 per cent., 93 per cent. of the eggs were fertile, and 80 per cent. of them hatched.

For 6 other groups part of the wheat and meatmeal was replaced by a mixture of alfalfa, bone and liver meals, buttermilk, and whey powders, bran and pollard or by alfalfa meal alone or with combinations of these feeds; for a seventh group pantothenic acid in the basal ration was increased to 10 p.p.m. In none of the groups did the results differ significantly from those for the group given the basal ration.

6. A breeding ration contained, per cent., ground wheat 61, meatmeal 8.5, bran 15, pollard 15, and salt 0.5 with vitamin A emulsion and 1 mg. riboflavin per lb. It was given unmodified or varied by adding a vitamin B complex mixture or by replacing 10 parts of wheat with 5 parts each of alfalfa meal and whey powder, or by removing the riboflavin. All the birds had access to shell grit. For the first 3 groups egg production, fertility and hatching capacity did not differ significantly, being, respectively, per cent., 52, 85, and 82; 55, 91 and 87; 54, 87 and 86. For the fourth group with riboflavin omitted the values, based on only one replication and excluded from the analysis, were 43, 78 and 28.

Chicks from hens in the 4 groups in the order just given were given standard mashers with 20 per cent. meatmeal, and the mean weight in g. and number of chicks were 104, 701; 106, 862; 109, 752, and 104, 61. In good conditions the mortality rates were 6, 6, 5 and 13 per cent., and in 2 hatches in which accidental chilling occurred

the rates were 19, 12, 5 and 11 per cent. The low mortality rate in the third group under the stress of cold, though not statistically significant, is considered as evidence that progeny from the groups getting alfalfa and whey powder did have greater resistance.—K. J. Carpenter.

MOURIQUAND, G., EDEL, V. and CHIGHIZOLA, R. Sur l'action antibériberique du monophosphate de thiamine. [Antiberiberic action of vitamin B₁ monophosphate.] *C.R. Soc. Biol.*, 1955, **149**, 131-132.

Vitamin B₁ monophosphate was tested with pigeons and proved to have an effect against beriberi comparable with that of the more commonly used vitamin B₁ chloride hydrochloride. It was less toxic than the hydrochloride if given in excessive doses even up to 1000 mg. An injection of 200 mg. vitamin B₁ chloride hydrochloride was rapidly fatal to pigeons.—A. M. Copping.

4863

GRANA, E. Azione immediata della vitamina B₁ e della cocarbossilasi sul Q.R. e sulla produzione calorica di ratti in avitaminosi B₁. [Immediate action of vitamin B₁ and of cocarboxylase on the respiratory quotient and heat production of rats deprived of vitamin B₁.] *Bol. Soc. ital. Biol. sper.*, 1953, **29**, 1781-1783. [Ist. Fisiol., Univ. Pavia.]

Heat production and R.Q. were measured in rats weighing from 60 to 70 g., deprived and not deprived of vitamin B₁, and before and 4 hr. after injection with 1 mg. or 50 µg. of vitamin B₁ or cocarboxylase. No difference was found between the effects of vitamin B₁ and of cocarboxylase. On injection of either substance, the R.Q.

rose and the heat production fell, more so in the deprived than in the non-deprived animals, except that with the smaller dose the effect on the R.Q. was slightly greater in the non-deprived rats.

E. M. Hume.

CASELLA, C. and DE CARO, L. G. Velocità di conduzione del potenziale d'azione dello sciatico di ratti trattati con neopirithiamina (NP). [Rate of conduction of action potential in the sciatic nerve of rats treated with neopyrithiamine.] *Bol. Soc. ital. Biol. sper.*, 1953, 29, 1779-1781. [Ist. Fisiol., Univ. Pavia.]

It had previously been found that deprivation of vitamin B₁ did not change the rate of conduction in nerve (Abst. 409, Vol. 24). The same tests were made with rats weighing from 75 to 85 g. given daily for from 5 to 7 days from 5 to 6 mg. neopyrithiamine. The rats lost weight rapidly, and the mean rate of transmission in the sciatic nerve was slower by 13.6 per cent. than in rats not given neopyrithiamine. The difference was significant. The previous failure to demonstrate retardation is ascribed to the incomplete depletion of vitamin B₁ in the nerve.—E. M. Hume.

4865

DE CARO, L. and RENDI, G. On the metabolic significance of blood pyruvate in B₁ avitaminosis. *Experientia*, 1955, 11, 196-197. [Inst. Human Physiol., Univ. Pavia.]

Recent work of Rindi *et al.* (Abst. 3020, Vol. 24) showed that the accumulation of pyruvate in the blood in vitamin B₁ deficiency could be directly correlated with the degree of adrenal hypertrophy. Blood pyruvate was estimated in rats deprived of vitamin B₁ for periods of up to 36 days and in deprived rats after adrenalectomy or hypophysectomy. The pyruvate content of the blood was significantly lower when the pituitary or adrenal glands had been removed. It is suggested that hyperfunction of the pituitary and adrenal system may partly explain the increase of pyruvate in the blood in vitamin B₁ deficiency but that retardation of oxidative mechanisms may slow down the process of removal from the blood. The question is discussed in relation to carbohydrate metabolism in rats deprived of vitamin B₁.—A. M. Copping.

sviluppo. [2. Pyruvic acid content of uncalcified cartilage in the developing rabbit.]

ZAMBOTTI, V. and LORENZI, G. L. 3. Presenza negli estratti di cartilagine preossea di un fattore inibente l'attività cocarbossilasi. [3. Presence in extracts of uncalcified cartilage of a factor inhibiting cocarboxylase.] *Bol. Soc. ital. Biol. sper.*, 1953, 29, 1953-1954; 1954-1955; 1955-1957. [Ist. Chim. Biol., Univ. Pavia.]

1. In young rabbits the concentration of cocarboxylase in proliferating cartilage was greater the more rapid the growth. In young Giant Belgian rabbits the concentration was especially high.

2. The mean concentration of pyruvic acid in proliferating cartilage of 11 rabbits, 20 days old, was 6.7 mg. per 100 g. fresh tissue. Variation was wide with a maximum value of 18. The concentration appeared to diminish with increasing age.

3. An acidified aqueous extract was prepared from proliferating cartilage of young rabbits. Cocarboxylase was estimated in one portion of the extract: to another portion a known amount of cocarboxylase was added, but on estimation the amount found was less than the sum of that added and that originally found present. The size of the deficit was greater, the smaller the amount of cocarboxylase found to have been originally present. On dialysis through a collodion membrane, all the cocarboxylase was recovered. An inhibitory factor of large molecular size was postulated in the cartilage extract. If the extract was boiled for 5 min. the effect was lost.—E. M. Hume.

MONFOORT, C. H. De invloed van thiamine deficiënte voeding op enige enzymen in de spieren van de duif. [The influence of a vitamin-B₁-deficient diet on some enzymes in the muscles of the pigeon.] *Thesis, Univ. Utrecht*, 1953, pp. 101. English summary.

Literature dealing with the activity of vitamin B₁ pyrophosphate as cocarboxylase in the several reactions in which it takes part is reviewed. The work is a continuation of that of Gruber and Meyer (Abst. 330, Vol. 21). Homogenates of pigeon muscle from breast, left ventricle and leg were incubated at 37°C. anaerobically with pyruvate, α -ketoglutaric acid, acetaldehyde or propionaldehyde, alone or with pyruvate at pH 6.2. CO₂ was estimated by Warburg's method.

The decomposition of pyruvate or pyruvate and acetaldehyde to give acetoin and CO₂ (pyruvic carboxylase), of acetaldehyde to give acetoin (acetaldehyde condensing enzyme) and of α -ketoglutarate to succinic semi-aldehyde and CO₂ (α -ketoglutaric carboxylase) is catalysed by enzymes containing vitamin B₁ pyrophosphate.

N.A. and R., October 1955

Comparison of muscle from pigeons on a diet rich in vitamin B₁ and from pigeons deprived of the vitamin for 4 or 12 days showed that the greater the concentration of vitamin B₁ pyrophosphate in the homogenate, the greater the formation of acetoin or succinic semi-aldehyde. (The acetaldehyde condensing series did not prove suitable for the work.) There was no uniform relation between the rate of disappearance of the pyrophosphate and the enzyme activity either in the several muscles or in the same muscle. Activity was always less in leg muscle. In general α -ketoglutaric carboxylase appeared to survive in vitamin B₁ deficiency longer than pyruvic carboxylase. The prosthetic group alone was lost; addition of the pyrophosphate to the homogenate restored full activity.—I. Leitch.

GOETHART, G. Cytochemische onderzoeken over het thiamine pyrophosfaat. [Cytochemical studies on vitamin B₁ pyrophosphate.] *Thesis, Univ. Utrecht*, 1953, pp. ix + 62. English summary.

Normal and vitamin-B₁-deprived rats and mice were used. Vitamin B₁ pyrophosphate was estimated in nuclear, mitochondrial, submicroscopic and soluble fractions of homogenised liver and mouse hepatoma. The occurrence of complications such as the decomposition of the pyrophosphate during the processing of tissues from the normal but not from the deprived animals is discussed. There were apparently 2 forms of the pyrophosphate of which one disappeared when the diet was deficient. If allowance was made for some degree of impurity of the fractions, it appeared that the pyrophosphate was present chiefly in the mitochondrial and soluble fractions; one fraction was not characterised by one form of the pyrophosphate. The amount in the soluble fraction did not depend on the strength of the solvent, and was not altered by removal of protein; pyrophosphate was not adsorbed on mitochondria or removed by the processing.

Tests in which homogenates and the several fractions from deprived rats were incubated anaerobically with Na pyruvate showed that addition of vitamin B₁ pyrophosphate significantly increased the production of acetoin and CO₂ by the homogenates, but only by the mitochondria and soluble fractions together. There was therefore no clear evidence that any vitamin B₁ pyrophosphate enzyme occurred in the soluble fraction. I. Leitch.

COLTORTI, M. and DELLA PIETRA, G. 3. Sulla liberazione di fosfati inorganici dall'ATP. [3. Liberation of inorganic phosphates from adenosine triphosphate.] *Bol. Soc. ital. Biol. sper.*, 1953, **29**, 1829-1831; 1831-1833; 1833-1834. [Ist. Chim., Fac. Med., Univ. Naples.]

1. Pigeons were maintained on a diet of polished rice till signs of deficiency appeared. In comparison with normal pigeons, the mean content of alkaline phosphatase was decreased in the cerebral hemispheres, cerebellum and optic lobes; it was increased in the liver, kidneys and heart muscle, but in pectoral muscle it was the same.

2. Acid phosphatase was estimated in the same way in the cerebral hemispheres, kidneys and liver. The mean amount was increased in the liver of deprived birds, but in the other tissues was unchanged.

3. In a similar experiment the mean amount of inorganic P liberated from adenosine triphosphate by pectoral muscle tissue was somewhat less in deprived than in non-deprived birds.

[Enzymic amidation of nicotinic acid in normal pigeons and pigeons deprived of vitamin B₁.] *Bol. Soc. ital. Biol. sper.*, 1953, **29**, 1907-1908. [Ist. Chim., Fac. Med., Univ. Naples.]

The capacity to convert ammonium nicotinate into nicotinamide was estimated in homogenates of kidney and liver from pigeons maintained on a diet of polished rice till signs of deficiency occurred, and from normal birds. In the deprived birds the capacity was greatly reduced.—E. M. Hume.

CERRECEDO, L. R. and EICH, S. Studies on thiamine analogues. 4. Neopyrithiamine and oxynopyrithiamine. A comparison of their effects *in vivo* and *in vitro*. *J. Biol. Chem.*, 1955, **213**, 893-897. [Dept. Biochem., Fordham Univ., New York.]

The 4-hydroxypyrimidyl derivative of neopyrithiamine was prepared and termed oxynopyrithiamine. The new compound did not inhibit the phosphokinase of adenosine triphosphate and vitamin B₁ in rat liver *in vitro* (cf. Abst. 4410, Vol. 24). In studies with mice it was observed that oxynopyrithiamine differed from neopyrithiamine in not inhibiting vitamin B₁ *in vivo*. It appeared that the inhibitory properties of

neo-pyrimthiamine were related to the presence of a 4-aminopyrimidyl group, and were lost when a 4-hydroxypyrimidyl group was substituted.

FUJITA, A., NOSE, Y. and KURATANI, K. The second type of bacterial thiaminase. *J. Vitaminol., Japan*, 1954, 1, 1-7. [Biochem. Inst., Kyoto Prefectural Univ. Sch. Med., Kawaramachi.]

A new thiaminase was obtained from *Bacillus aneurinolyticus*, Kimura and Aoyama, and was found to differ from the enzyme obtained from *B. thiaminolyticus*, Matsukawa and Misawa. The new enzyme split vitamin B₁ into its thiazole and pyrimidine components and was not activated by aniline, pyridine, quinoline or other amines which activate the thiaminases previously described. The name thiaminase II is suggested for the enzyme, which has the additional property of forming a base-exchanged pyrimidine derivative from pyrimidinmethanol and a base such as aniline.—A. M. Copping.

MATSUKAWA, T. and YURUGI, S. On thiamine destructive factor. *J. Vitaminol., Japan*, 1954, 1, 27-38. [Res. Lab., Takeda Pharmaceutical Industries, Ltd., Osaka.]

Chemical degradation of vitamin B₁ was obtained in the presence of sulphurous acid in aqueous solution. The reaction was accelerated by addition of pyridine, quinoline, nicotinic acid, aniline, *p*-aminobenzoic acid or indole and, at the same time, the thiazole portion of the molecule was replaced by the amine compound. The reaction depended on pH, and in many respects the action of sulphurous acid resembled that of a thiaminase.

MATSUKAWA, D., CHANG, S., MISAWA, H., FUJIMIYA, M., KOBAYASHI, N., HORIKAWA, Y. and TAKATO, K. Studies on the thiamine deficiency due to bacterial thiaminase. 1. Investigations on intestinal contents. *J. Vita-*

minol., Japan, 1954, 1, 43-48. [Dept. Med., Niigata Univ. Sch. Med., Asahi-machi.]

Thiaminase activity found in the faeces of patients with beriberi or gastro-intestinal disorders was associated with *Bacillus thiaminolyticus*, Matsukawa and Misawa. In 2 patients examined at autopsy, the enzyme occurred mainly in the lower ileum, caecum, colon and rectum. In patients with thiaminase activity in the gut, ingested vitamin B₁ was rapidly destroyed and little was excreted in the urine or faeces.

When 29 healthy subjects were given *B. thiaminolyticus* by mouth only 2 showed thiaminase in the faeces, and it disappeared within 12 days. It was considered that the organism could not grow in the intestine of most healthy persons.

HAWK, E. A. and MICKELSEN, O. Nutritional changes in diets exposed to ethylene oxide. *Science*, 1955, 121, 442-444. [Lab. Biochem. Nutrit., Nat. Insts. Health, Bethesda, Md.]

Rats fed on purified and stock diets which had previously been exposed to ethylene oxide lost weight and some died with their visible stores of fat completely depleted. The treated purified diet was found to be deficient in vitamin B₁. Vitamin B₁ dispersed in starch and treated with ethylene oxide retained its full activity but was destroyed when choline chloride was present. Two groups of rats fed on the treated purified diet with added untreated vitamin B₁ or on a diet deficient in vitamin B₁, similarly treated but with no additional vitamin B₁, did not at first gain weight; later the first group did so, but not as much as rats on an untreated diet. With the treated stock diet, addition of vitamin B₁ or a complete vitamin mixture did not stimulate growth significantly; vitamin B₁ was thought not to be the only substance affected. It is suggested that foods should not be treated with ethylene oxide until the full effects of it have been ascertained.

riboflavin-5'-phosphate. *J. Amer. Pharm. Assoc.*, 1955, **44**, 1-5. [Nutrit. Labs., Hoffman-La-Roche, Inc., Nutley, N.J.]

Further confirmation was obtained of the full biological activity of synthetic riboflavin-5'-phosphate in promoting growth of weanling rats when given by mouth or intramuscular injection in curative or prophylactic tests, and in microbiological estimations by the method of Snell and Strong. By comparing its excretion after oral doses with that of riboflavin it was found to be completely available to human beings also. As it is more easily destroyed than riboflavin, careful protection from light must be ensured. Acid hydrolysis also destroys it and the phosphate group is rapidly split away from it by enzymic hydrolysis with clarase at pH 4.5 and 45° C.

RODRIGUEZ, N. M. and CERECEDO, L. R. Changes in the size of certain organs of tumor-bearing rats, and the protective effect of riboflavin in rats fed 4-dimethylaminoazobenzene. *Growth*, 1955, **19**, 31-37. [Dept. Biochem., Fordham Univ., New York.]

In rats receiving 4-dimethylaminoazobenzene in the diet, the spleen, liver, kidneys, lungs and testes were enlarged in relation to bodyweight. The effect of the carcinogen on the size of all the organs except the testes was counteracted when a large excess of riboflavin was included in the diet. Enlargement of the spleen, liver and lungs, but not of the kidneys and testes, occurred also in rats bearing Walker carcinoma 256. Enlargement of the spleen was seen in rats with tumours in size up to 30 per cent. of bodyweight; when the tumour was larger the relative size of the spleen

decreased. With tumours amounting to more than 25 per cent. of bodyweight the size of the lungs decreased.—A. M. Copping.

SESSA, T. and FUSCO, M. La riboflavinemia nella intossicazione acuta sperimentale da tallio. [Blood riboflavin in acute experimental thallium poisoning.] *Acta vitaminol.*, 1955, **9**, 14-16. [Ist. Med. Lavoro, Univ. Naples.] French, English, German and Spanish summaries.

The signs of thallium poisoning are considered to be reminiscent of those of riboflavin deficiency.

Riboflavin was estimated by a fluorescence method in the blood of 7 rabbits weighing about 2 kg., before and after administration on alternate days of an oral dose of 0.2 g. thallium carbonate. The animals did not survive more than 3 doses. The values for riboflavin in the blood were on the average 15 per cent., range from 11.1 to 20 with one value of 48 per cent., lower after than before administration of thallium.—E. M. Hume.

TERRILL, S. W., AMMERMAN, C. B., WALKER, D. E., EDWARDS, R. M., NORTON, H. W. and BECKER, D. B. Riboflavin studies with pigs. *J. Animal Sci.*, 1955, **14**, 593-603. [Illinois Agric. Exp. Stat.]

With a purified diet containing only 0.05 mg. riboflavin per lb., 3 groups of 6 weanling pigs were given 0.8 or 1.4 mg. riboflavin per lb. feed or no addition. The trial was preceded by a depletion period of 2 weeks on the purified diet and lasted for 7 weeks. Weight increase and feed consumption were significantly greater in the groups given added riboflavin and, when adjusted for feed intake, the weight increase was still significantly higher. Between the groups given riboflavin there was little difference. Blood counts showed no difference.

In a second experiment 3 groups of 6 pigs received the purified diet with supplements of 0.6, 0.8 or 1.0 mg. riboflavin per lb. feed. There was no significant difference between the groups in feed consumption or final weight.

Supplements of 10 mg. chlortetracycline, 15 µg. vitamin B₁₂, and 0.4 mg. or 1.2 mg. riboflavin, per lb. feed, alone or together, were compared in a

third experiment. Weight increase with 0.4 mg. riboflavin only was significantly less than with the other supplements before adjustment for feed intake, but not after, which suggested that most of the pig's weight response to riboflavin is related to voluntary intake of feed. During the first half of the experiment chlortetracycline caused a significant increase in weight, before adjustment for feed intake. There was no significant interaction between treatments, and it was concluded that the antibiotic and vitamin B₁₂ did not influence the riboflavin requirements of pigs. The requirement of a weanling pig for riboflavin is suggested as about 0.6 mg. per lb. feed, in the readily available form used in the experiments. In normal feeds it may not be so readily available, and to be satisfactory the feed might have to yield greater amounts on analysis.—T. D. Bell.

VILLELA, G. G., MITTIERI, E. and RIBEIRO, L. P. Flavoproteins in the blood plasma of the Brazilian snake *Bothrops jararaca*. *Arch. Biochem. Biophys.*, 1955, 56, 270-273. [Biochem. Lab., Inst. Oswaldo Cruz, Rio de Janeiro, Brazil.]

Fresh or dried samples of venom from *Bothrops jararaca* were almost devoid of xanthine oxidase activity as measured manometrically, and molybdenum was not detected spectrographically. Results showed also that the flavins of blood plasma from *B. jararaca* were linked to the protein fractions in the form of flavin adenine dinucleotide bound only to the L-amino-acid oxidase, since no xanthine oxidase activity was detected. The liver of the snake was poor in xanthine oxidase activity, compared with rat liver.—G. F. Garton.

NICOTINIC ACID (NIACIN)

4886

FISHER, H., SCOTT, H. M. and JOHNSON, B. C. Liver pyridine nucleotide content as related to dietary tryptophan and nicotinic acid in the chick. *Arch. Biochem. Biophys.*, 1955, 56, 130-136. [Div. Animal Nutrit., Dept. Animal Sci., Illinois Agric. Exp. Stat., Urbana.]

Four groups of 7 chicks were given a synthetic basal diet containing no nicotinic acid and 0.15 per cent. tryptophan, the amount found in an earlier experiment (Title 1952, Vol. 25) to be the minimum required by chicks when nicotinic acid was adequate. Three of them were given in addition 0.15 per cent. nicotinic acid, or 0.25 per cent. tryptophan, amounts which are equimolecular, or both. After 3 weeks the average bodyweights for the untreated and treated groups in that order were 126, 157, 147 and 142 g. The birds were killed and pyridine nucleotide was estimated in the liver; mean values for the groups in the same order were 502, 885, 608 and 1457 μ g. per g. fresh tissue.

Livers were analysed also from birds in the earlier experiment (Title 1952, Vol. 25) which was of factorial design with levels of nicotinic acid 0, 2.5, 5, 10 and 20, and of tryptophan 0.1, 0.15, 0.2, 0.3 and 0.4, mg. per 100 g. diet. The level of pyridine nucleotide did not rise as the nicotinic acid was increased but in some groups it was greater with the larger amounts of tryptophan.

It was concluded that in equimolecular amounts nicotinic acid was more efficient than tryptophan in promoting storage of pyridine nucleotide in the liver of chicks but that in ordinary amounts more was contributed to the storage of pyridine nucleotide by tryptophan than by nicotinic acid.

McDANIEL, E. G., HUNDLEY, J. M. and SEBRELL, W. H. Niacin and anti-niacin activity of 3-acetylpyridine in dogs. *J. Nutrition*, 1955, 55, 623-637. [Nat. Inst. Health, Bethesda, Md.]

The effect of 3-acetylpyridine was studied in dogs having maize or purified diets which produced blacktongue unless nicotinic acid was given. A daily dose of from 25 to 260 mg. 3-acetylpyridine protected dogs from blacktongue over long periods, and daily doses of from 25 to 60 mg. were curative. Urine analysis showed that 3-acetylpyridine had about one-sixth of the activity of nicotinic acid in increasing urinary excretion of N¹-methylnicotinamide in normal dogs having a stock diet. In dogs deficient in nicotinic acid, ability to convert 3-acetylpyridine to nicotinic acid was decreased, as was shown by the small amount of N¹-methylnicotinamide excreted. Large doses of 3-acetylpyridine were toxic for deficient dogs but were tolerated by normal dogs; the toxic effects were prevented if nicotinic acid was given at the same time, but could not be overcome once toxic signs had developed. It seemed that 3-acetylpyridine had activity for dogs both as nicotinic acid and anti-nicotinic-acid, according to the size of the dose and the state of the animals.—A. M. Copping.

KHADES, S. I. O mekhanizme deisviya nikotinovi kisloty. [Mode of action of nicotinic acid.] *Vop. Pitn.*, 1955, 14, No. 2, 13-16. [Inst. Med., Archangel.]

Previous work has shown that nicotinic acid, apart from its role as a coenzyme, has a number of secondary effects including changes in carbohydrate metabolism, small doses depressing and larger doses raising the blood sugar level. The hypothesis that a nervous reflex is involved was tested by injecting into the ear veins of rabbits nicotinic acid with novocaine, and again with atropine, and estimating the blood sugar. With novocaine small doses of nicotinic acid, 1 mg. per kg., caused no change, larger doses, 10 mg. per kg., a slight fall of blood sugar. With atropine small doses caused a marked rise and large doses a considerable fall followed by a rise. The results are taken to imply involvement of vascular chemoreceptors and of a parasympathetic effector pathway in the changes caused in carbohydrate metabolism by nicotinic acid.—D. W. Taylor.

4890

VILLA, L. and DI GUARDI, N. Studies on factors influencing the endogenous respiration of liver homogenates. The action of nicotinamide on a keto-oxidase activity of rat's liver. *Experientia*, 1955, 11, 31-33. [Inst. Clin. Gen. Med., Univ. Milan.]

The endogenous respiration of homogenates of liver from rats having a balanced diet or a high protein or high fat intake was studied by a manometric method. The effect reported (Abst. 3038, Vol. 24) of nicotinamide in increasing endogenous respiration occurred only in livers from rats having a high-fat diet or in rats fasting from a normal diet. In a series of tests with different substrates, the marked increase in respiration in presence of nicotinamide was obtained only with acetoacetate. It was therefore postulated that the increased respiration was due to the activity of a keto-oxidase system in the liver.

L'ABBATE, S. Influenza degli estratti epatici, dell'acido nicotinico e degli estratti epatici associati ad acido nicotinico sulla solfoconjugazione. [Influence of liver extracts, of nicotinic acid, and of the two together, on sulphur conjugation.] *Bol. Soc. Ital. Biol. sper.*, 1953, 29, 1342-1344. [Ist. Farmacol., Univ. Catania.]

Free and conjugated S were estimated daily for 10 days in the 24-hr. urine of 4 rabbits weighing 1.5 kg., maintained on a constant, normal diet. For successive periods the animals were given a daily subcutaneous injection of 0.04 mg. resorcinol, or 0.03 g. nicotinic acid per kg. bodyweight, or an

intramuscular injection, per kg. bodyweight, of 1 ml. of liver extract Epatol Dessy, equivalent to 300 g. fresh liver, or the same substances in pairs or all 3 together. The total amount of S in the urine did not vary greatly with the 3 substances, but the proportion of conjugated S was increased by all the substances; they reinforced the effect of one another and were most effective when given all 3 together.—E. M. Hume.

BRAUDE, R., KON, S. K., MITCHELL, K. G. and KODICEK, E. Maize and pellagra. *Lancet*, 1955, 268, 898-899. [Nat. Inst. Res. Dairying, Univ. Reading.]

There is evidence that the nicotinic acid present in maize and other cereals is in a bound form, not available for the rat or chick or for the growth of lactobacilli. The full biological activity can be released by hydrolysis with 0.5 N NaOH (see Abst. 3189, Vol. 14).

In the present work 18 weanling pigs from 4 litters, of weight from 37 to 59 lb., received, for a preliminary period, a pellagra-producing diet of, per cent., ground white maize 79, pea meal 10.5, purified casein 5, cod liver oil 3, and salt mixture 2.5 (see Absts. 4778, Vol. 7; 363 and 1850, Vol. 8). When growth ceased they were divided into 3 groups of 5 or 6; the first continued on a diet which was similar to the previous one, but in which the maize constituent was reconstituted from a complete series of milling fractions; the second group received in addition 6 mg. nicotinic acid daily. The third group had a diet like that of the first group except that the milling fraction which contained most of the aleurone layer and 73 per cent. of the total nicotinic acid (see Abst. 449, Vol. 22) had been hydrolysed for 30 min. with 0.5 N NaOH. The pigs continued to receive the diets for 9 weeks or until they succumbed.

During the preliminary period 17 of the 18 pigs showed signs of nicotinic acid deficiency within from 17 to 63 days; one pig became deficient only after 13 weeks and was not included in the experiment proper.

The deficient pigs in the first group on the average showed no weight increase; 2 died before the fifth week, 2 became moribund by the ninth week and 2 completed the period without signs of deficiency. All the pigs in the second group, given nicotinic acid, recovered from their previous state of deficiency and gained steadily in weight.

The pigs in the third group, receiving the alkali-hydrolysed maize fraction, also recovered but ate less and gained weight more slowly than those given nicotinic acid.

It was calculated that for the pigs in the preliminary period and for those in the 3 groups in the order above, the average daily intake of nicotinic acid was, respectively, 10.8 mg. almost all unavailable, 7.7 mg. with 0.8 mg. available, 20.8 mg. with 7.6 mg. available, and 12.6 mg. with 9.6 mg. available.

It is concluded that the recovery of the pigs in the third group was related to the availability of the nicotinic acid after hydrolysis, as had been shown for rats. The suggestion is repeated that the lime-water treatment of maize, as practised in Mexico, may be responsible for the low incidence of pellagra among maize eaters in that country (see also Absts. 4195, Vol. 16; 4804, Vol. 21; 2921, Vol. 23; Title 5184, Vol. 24).—H. Chick.

SUNDE, M. L. **The niacin requirement of chickens from 6 to 11 weeks.** *Poultry Sci.*, 1955, **34**, 304-311. [Poultry Dept., Univ. Wisconsin, Madison.]

In 4 experiments extending over 2 years, chicks were given from the 6th to the 11th week of age a basal diet low in nicotinic acid and containing either dextrin or sucrose, and casein, gelatine, soya bean oil, methionine, choline, minerals and vitamins. The diet contained, per cent., protein 21 and tryptophan 0.21, and 1.8 mg. nicotinic acid

per kg. Supplements of nicotinic acid, from 5 to 50 mg. per kg. diet, were given. After 2 weeks of the unsupplemented basal diet growth was retarded; after 3 weeks chicks receiving the 5 mg. supplement also showed slow growth. The combined results of the 4 experiments showed that from the 6th to the 11th week of age the chicks required between 7 and 12 mg. available nicotinic acid per kg. diet for optimum growth. In practical rations a certain amount of the nicotinic acid present may be in bound form and unavailable to the chick; it is, therefore, suggested that such rations should be supplemented with 5 mg. nicotinic acid per kg., even after the chicks are 6 weeks old.—E. M. Cruickshank.

CHIANG, Y. T. **Chemotherapy of murine leprosy. 3. The effects of nicotinamide and pyrazinamide (aldinamide) on mouse leprosy.** *Internat. J. Leprosy*, 1954, **22**, 331-346. [Nat. Inst. Arthritis and Metabol. Dis., Nat. Insts. Health, Bethesda, Md.] Spanish summary.

Groups of 20 female mice weighing about 20 g. were inoculated intraperitoneally with *Mycobacterium leprae murium*, and were treated with the drug to be tested from 1 day or 1 month or 2 months after the inoculation. The drugs were mixed with the food except for streptomycin which was injected subcutaneously 5 times a week. After 3 months after inoculation the mice were killed and the degree of protection was assessed from the mortality rate and from the autopsy findings. Nicotinamide, pyrazinamide and isoniazid had the highest activity in suppressing murine leprosy; streptomycin was less active and 4, 4'-diaminodiphenylsulphone was the least effective. The substances were most effective when given from the time of inoculation. They had some activity when started a month later but very little when given for a month after an interval of 2 months.

STEPANTSCHITZ, G. and WAGNER, K. **Die Wirkung von Vitamin B₆ auf den Ablauf experimenteller hämolytischer Anämien. [Effect of vitamin B₆ on the course of experimental haemolytic anaemia.]** *Klin. Wochenschr.*, 1955, **33**, 70-72. [Med. Klin., Univ. Graz.]

Haemolytic anaemia was produced in 8 groups of 6 rats by the intramuscular injection of from

0.5 to 2 ml. serum from rabbits previously sensitised to rat's blood; the serum had a high titre of haemolysin and agglutinin. In each group 2 rats were untreated, 2 received 50 mg. vitamin B₆ (Benadon) daily, and 2 Antihistaminica. Previous work had shown that serum from untreated rabbits had no effect on the blood picture of rats. All the rats injected with the serum developed a severe haemolytic crisis associated with a marked drop in the red cell count which, in the untreated animals, fell to 1 million with haematuria and changes in the kidney. In the untreated animals which survived, the blood picture returned to normal in from 2 to 3 weeks. In the animals treated with vitamin B₆ the fall in the red cell count was slightly less and the return to normal more rapid. In the doses used, Antihistaminica had no effect on the anaemia. The mode of action of vitamin B₆ is discussed.

BEATON, J. R. Further studies on carbohydrate metabolism in the vitamin-B₆-deprived rat. *Canad. J. Biochem. Physiol.*, 1955, **33**, 161-166. [Dept. Pub. Health Nutr., Sch. Hyg., Univ. Toronto.]

Young rats were given for 1 or 3 weeks a purified diet containing 20 per cent. casein, 20 per cent. fat and no vitamin B₆. Pair-fed rats had the same diet with 50 µg. pyridoxine daily. After fasting for 24 hr. the animals were anaesthetised with Nembutal and blood was taken from the exposed heart for estimation of glutathione, inorganic and acid-soluble phosphorus, and sugar. Liver and muscle also were analysed in some tests. Significant increases were found in the inorganic P and glutathione in the blood and liver from rats deprived of vitamin B₆ for 3 weeks, and in the blood after only 1 week. No significant change in muscle glycogen was found. In deprived rats the changes in the blood sugar value in response to insulin or alloxan were slightly greater than in pair-fed, non-deprived rats.—A. M. Copping.

HOLT, C. V., HEINRICH, W. D. and HOLT, L. v. Zur Frage der diabetogenen Wirkung der Xanthurensäure. [Diabetogenic action of xanthurenic acid.] *Hoppe-Seyler's Ztschr.*, 1954, **297**, 241-246. [Physiol. Chem. Inst., Univ. Hamburg.]

Vol. 25, No. 4

A single injection of 200 mg. xanthurenic acid per kg. bodyweight caused no significant rise in the blood sugar of rats receiving a complete, purified diet. Repeated injections during 14 days had no effect on blood sugar or on the beta cells of the islets of Langerhans. No rise in blood sugar occurred when large doses of tryptophan and butyrate were given by mouth. In rats deprived of vitamin B₆ administration of tryptophan and butyrate produced a small temporary increase in blood sugar, but no degenerative changes could be detected in the beta cells of the islets of Langerhans.—A. M. Copping.

9. See Abst. 3529, Vol. 25.

10. Groups of from 5 to 7 male rats weighing about 150 g. were given a diet of, per cent., casein 22, starch 52, yeast 2, agar 3, salt mixture 6, butter 10 and sucrose 5. One group was injected intraperitoneally with 200 mg. xanthurenic acid and another was given adrenaline. Blood sugar was estimated every 30 min. After from 3 to 4 hr., when the hyperglycaemic phase had begun in the rats given xanthurenic acid, they were all killed and the blood was collected. The average value for glutathione in the blood of the rats given xanthurenic acid was about half that in the groups given adrenaline or no treatment.

Administration of 50 mg. isonicotinic acid hydrazide per 100 g. diet did not affect the growth or the metabolism of nicotinic acid in rats having diets with or without nicotinic acid. In vitamin B₆ deficiency isonicotinic acid hydrazide inhibited growth, decreased survival time and hastened the onset of convulsions. The increased excretion of

xanthurenic acid after administration of tryptophan, which is characteristic of vitamin B₆ deficiency, did not occur when isonicotinic acid hydrazide was given.—A. M. Copping.

LICHSTEIN, H. C. Mechanism of competitive action of isonicotinic acid hydrazide and vitamin B₆. *Proc. Soc. Exp. Biol. Med.*, 1955, 88, 519-522. [Dept. Bacteriol., Univ. Minnesota, Minneapolis.]

A study was made of the effect exerted by isonicotinic acid hydrazide on tryptophanase activity in a mutant of *Bacterium coli* which required vitamin B₆. Inhibition of tryptophanase activity occurred in living cells and in dried preparations, except when the cells had been previously incubated with pyridoxal and the dried preparations with pyridoxal phosphate. The reaction between pyridoxal phosphate and isonicotinic acid hydrazide was competitive and depended on the relative concentrations of the two substances. It is suggested that it is for the apoenzyme of tryptophanase that isonicotinic acid hydrazide competes with pyridoxal phosphate.—A. M. Copping.

MARSH, M. E., GREENBERG, L. D. and RINEHART, J. F. The relationship between pyridoxine ingestion and transaminase activity. 1. Blood hemolysates. *J. Nutrition*, 1955, 56, 115-127. [Dept. Pathol., Univ. California Sch. Med., San Francisco.]

The method of Tonhazy *et al.* (Title 3155, Vol. 20) for estimating aspartic-glutamic transaminase was adapted for blood samples from monkeys and man. Administration of graded doses of pyridoxine hydrochloride to monkeys produced corresponding increases in the concentration of vitamin B₆ and transaminase in the blood. The fall in transaminase was slower than in vitamin B₆ when the vitamin was withdrawn. Similar effects were observed with healthy human subjects receiving doses of from 10 to 15 mg. pyridoxine daily.

The transaminase activity of blood haemolysates from monkeys deprived of vitamin B₆ was not increased by addition of pyridoxal phosphate or pyridoxamine phosphate; this, it is suggested, may be due to the presence in the blood of an active phosphatase that cleaves the phosphorylated forms of vitamin B₆.—A. M. Copping.

BERGERET, B., CHATAGNER, F. and FROMAGEOT, C. Quelques relations entre le phosphate de pyridoxal et la décarboxylation de l'acide cystéinesulfonique par divers organes du rat normal ou du rat carencé en vitamine B₆. [Relations between pyridoxal phosphate and the decarboxylation of cysteine sulphonic acid by different organs of the normal or vitamin-B₆-deficient rat.] *Biochim. biophys. Acta*, 1955, 17, 128-135. [Lab. Chim. Biol., Fac. Sci., Paris.] English and German summaries.

The comparative rates of decarboxylation of cysteine sulphonic acid, cysteic acid and glutamic acid were studied under controlled conditions in the presence of homogenates of brain and liver tissue from normal rats, and rats deprived of vitamin B₆ with or without addition of pyridoxal phosphate. With tissue from normal rats the effect of adding coenzyme in the form of pyridoxal phosphate was very slight with liver tissue but marked with brain preparations. Deficiency of vitamin B₆ caused disappearance of apodecarboxylase from the liver but no decrease in the brain; regeneration of it occurred in rats receiving vitamin B₆ after a period of deprivation. Cysteine sulphonic acid was always decarboxylated more rapidly than cysteic acid, a finding held to support the view that, in the rat, taurine arises from oxidation of hypotaurine rather than from decarboxylation of cysteic acid.—A. M. Copping.

OLIVARD, J. and SNELL, E. E. Growth and enzymatic activities of vitamin B₆ analogues. 1. D-Alanine synthesis. 2. Synthesis of miscellaneous amino acids. *J. Biol. Chem.*, 1955, 213, 203-214; 215-228. [Biochem. Inst., Univ. Texas, Austin.]

1. The effect of vitamin B₆ analogues on *Streptococcus faecalis* R was studied in tests in which growth was limited by the ability to synthesise D-alanine from L-alanine by means of alanine

racemase (cf. Absts. 3251, Vol. 17; 4283, Vol. 23). Equivalent growth, measured as dry cell production, was obtained by addition to the basal medium of, in μ moles per 6 ml., pyridoxal 0.003, ω -methylpyridoxal 0.10 or D-alanine 4000. Growth was promoted also by ω -methylpyridoxamine and its 5-phosphate and the 5-phosphate of ω -methylpyridoxal. The maximum rate of racemisation obtained with ω -methylpyridoxal phosphate as coenzyme was less than with pyridoxal phosphate but was increased if the concentration of L-alanine in the medium increased. The comparative affinities of coenzyme and analogue coenzyme for the aporacemase determined the effect of increasing the L-alanine content of the medium. The coenzyme as well as the protein appeared to be important in forming the enzyme substrate complex.

Several analogues of vitamin B₆ competitively inhibited activation of the cell-free racemase by pyridoxal phosphate and also inhibited growth of *S. faecalis* R. Enzyme-inhibitor dissociation constants for the alanine racemase of *S. faecalis* were calculated for 4-nitrosalicylaldehyde, 5-deoxypyridoxal, pyridoxal, ω -methylpyridoxal, pyridoxamine, ω -methylpyridoxamine and pyridoxine. In the conditions of the experiment 4-deoxypyridoxine and its phosphate did not inhibit growth or aporacemase activity.

2. In media containing excess of D-alanine but lacking other single amino-acids, capacity to synthesise the missing amino-acid became the limiting factor for growth of *S. faecalis*, and was shown to depend on the presence of vitamin B₆ or certain of its analogues. In conditions that required synthesis of the L-isomer of leucine, isoleucine, valine, phenylalanine, tyrosine, methionine or serine, growth of *S. faecalis* was supported by ω -methylpyridoxal, ω -methylpyridoxamine and

ω -methylpyridoxamine phosphate with activity ranging from 4 to 25 per cent. of that of pyridoxal or pyridoxamine. The ω -methyl analogues inhibited the growth-promoting activity of vitamin B₆ in media lacking L-cysteine. The cell-free transaminases corresponding with phenylalanine, tyrosine and leucine were activated by pyridoxal phosphate and its ω -methyl analogue; the affinities of the two coenzymes varied considerably for the three enzymes. ω -Methylpyridoxal phosphate was almost inactive in the cysteine desulphhydrase system and was much less active than pyridoxal phosphate in the tyrosine-glutamic acid transaminase system. In the discussion the importance is stressed of steric factors as well as of protein structure in determining the relative affinities of coenzyme and apoenzyme in the reactions studied.—A. M. Copping.

TOMARELLI, R. M., SPENCE, E. R. and BERNHART, F. W. Biological availability of vitamin B₆ of heated milk. *J. Agric. Food Chem.*, 1955, **3**, 338-341. [Res. and Development Dept., Nutrit. Div., Wyeth Laboratories, Inc., Mason, Mich.]

The vitamin B₆ potency of fresh milk, heated milk and infant foods was measured by tests with rats and with *Saccharomyces carlsbergensis*. Heated liquid milk and sterilised liquid infant food gave lower values for vitamin B₆ with rats than in microbiological tests, but values in good agreement were obtained for fresh milk and for a spray-dried, powdered infant food. The possibility is discussed that heat sterilisation of liquid infant foods may lead to deficiency of vitamin B₆.

PANTOTHENIC ACID

4914

BROWN, G. M., IKAWA, M. and SNELL, E. E. Synthesis and microbiological activity of some pantothenic acid conjugates. *J. Biol. Chem.*, 1955, **213**, 855-867. [Biochem. Inst., Univ. Texas, Austin.]

Various pantothenic acid conjugates were synthesised from pantoil lactone and the sodium salts of the appropriate β -alanyl peptides. The growth-promoting activity of pantothenamide, pantothenylglycine, pantothenylleucine and pantothenylhistidine for *Acetobacter suboxydans* and for some lactic acid bacteria was compared with that of other pantothenic acid derivatives. Most derivatives were active for *A. suboxydans* but only pantothenic acid, pantetheine and 4'-phosphopante-

theine had high activity for *Lactobacillus helveticus* 80, *L. acidophilus*, *L. casei* and *L. arabinosus* 17-5. The growth-promoting activity of pantothenic conjugates for *A. suboxydans* was associated with the occurrence of hydrolysing enzymes in cell-free extracts from cultures of the organism. The relation of the findings to suggested schemes for the biosynthesis of coenzyme A is discussed.

FIRKET, H., MOUCHETTE, R. and CHÈVREMONT, M. Comparison de l'action de dérivés du coenzyme A sur la croissance des cellules en culture de tissus. [Comparison of the action of derivatives of coenzyme A on the growth of cells in tissue culture.] *Bull. Soc. Chim. biol.*, 1955, **37**, 155-159. [Inst. Histol., Fac. Méd., Liège.] Growth and mitosis in conjunctiva and muscle tissue from chick embryos was inhibited by cysteamine but favoured by pantothenic acid at all concentrations. Pantetheine favoured growth in very low concentrations of from 1 in 15,000 to 1 in 20,000, but in greater amounts it had an inhibiting effect, due possibly to release of cysteamine by hydrolysis in the culture. A preparation of coenzyme A was toxic because of impurities and no result was obtained with direct tests. Low concentrations of pantetheine were more active than similar concentrations of pantothenic acid, and it is suggested that the tissues convert the first into coenzyme A more readily than the second.—A. M. Copping.

BUTLER, L. C. and MORGAN, A. F. The content of adrenocorticotrophic hormone in the pantothenic acid-deficient female rat. *Endocrinology*, 1955, **56**, 322-326. [Dept. Home Econ., Univ. California, Berkeley.]

A diet lacking in pantothenate was given to lactating rats when their young were 14 or 15 days old and subsequently to the female young of the

litters. At the age of 50 days the pituitary and a sample of venous blood were removed and the content of adrenocorticotrophic hormone was estimated biologically with hypophysectomised rats. In comparison with normal or pair-fed rats no decrease in the amount of adrenocorticotrophic hormone was found in rats deprived of pantothenate and not subjected to any stress.

ZUCKER, L. M., SERONDE, J. (Jr.), and ZUCKER, T. F. Acetylating activity in the rat in relation to other signs of pantothenic acid deficiency. *Arch. Biochem. Biophys.*, 1955, **55**, 9-18. [Dept. Pathol., Columbia Univ., New York.]

Acetylating mechanisms, as measured by the urinary excretion of acetylated products of sulphanilamide 1, 2, 3, 4 and 23 hr. after administration of 30 mg. sulphanilamide, were studied in rats deprived of pantothenic acid at weaning or when adult. Deprivation during 15 weeks caused progressive decrease in acetylating capacity. The shape of the acetylation time curves was similar in young and adult rats although other signs of pantothenate deficiency were different in the two age groups. Weanling rats deprived of pantothenate showed increased susceptibility to infection with corynebacterium, and adult rats developed duodenal ulcers (*cf.* Absts. 3404, Vol. 19; 4450, Vol. 24).—A. M. Copping.

- KRATZER, F. H., DAVIS, P. N., MARSHALL, B. J. and WILLIAMS, D. E. **The pantothenic acid requirement of turkey hens.** *Poultry Sci.*, 1955,

34, 68-72. [Dept. Poultry Husb., Univ. California, Davis.]

In experiments extending over 3 years, turkey hens received a basal diet containing, per kg., about 3.2 mg. pantothenic acid. The hatching capacity of the eggs fell from 57 per cent. to zero in about 5 weeks, but egg production was not affected. A supplement of 16 mg. pantothenic acid per kg. diet was required to maintain optimum hatching capacity. The survival of the poults and the free pantothenic acid content of the eggs were directly related to the amount of pantothenic acid in the diet. When the amount was 16 mg. per kg. diet the eggs contained about 11 μ g. per g. Most of the embryos that failed to hatch were from hens having the unsupplemented basal ration. They had wry down and abnormalities of the legs were frequent.—E. M. Cruickshank.

4926

- FISCHER, J. E. **Metabolism of β -methyl- C_5 fatty acids by mitochondria of rat liver: effect of biotin nutriture.** *Proc. Soc. Exp. Biol. Med.*, 1955, **88**, 227-230. [Inst. Enzyme Res., Univ. Wisconsin.]

Suspensions of liver mitochondria from mature, normal rats and from rats having a diet deficient in biotin were used to study the metabolism of isovalerate, 3-methyl-2-butenate, 3-methyl-3-butenate, n -valerate, α -methylbutyrate and n -caprylate in a medium containing KCl, Mg^{++} , phosphate

buffer and adenosine triphosphate. With mitochondria from normal livers, acetoacetate was readily formed from n -valerate and n -caprylate but addition of bicarbonate was required for metabolism of the two 3-methyl compounds and of isovalerate; malonate inhibited metabolism of the last 3 compounds. Mitochondria from rats deprived of biotin could metabolise n -valerate, α -methylbutyrate and n -caprylate but not isovalerate, 3-methyl-2-butenate or 3-methyl-3-butenate.—A. M. Copping.

YOUNG, R. J., NORRIS, L. C. and HEUSER, G. F. The chick's requirement for folic acid in the utilization of choline and its precursors betaine and methylaminoethanol. *J. Nutrition*, 1955, **55**, 353-362. [Dept. Poultry Husb., Agric. Exp. Stat., Cornell Univ., Ithaca, N.Y.]

Chicks were given a basal diet containing 16 μ g. folic acid per 100 g. and less than 0.007 per cent. of choline; addition of folic acid did not prevent perosis. Inclusion of 0.05 per cent. choline reduced the incidence slightly, but even 0.8 per cent. did not completely prevent perosis or give maximum growth. When the diet was supplemented with folic acid, addition of 0.05 per cent. of choline appeared to be adequate. When the diet contained sufficient choline, about 30 μ g. of added folic acid per 100 g. was required; when the dietary choline was suboptimum, folic acid had to be increased to 80 μ g. per 100 g. diet. Choline was essential for preventing perosis even in presence of large amounts of folic acid. Monomethylaminoethanol combined with betaine was utilised as efficiently as an equimolar concentration of choline, whether folic acid was present or not. Folic acid was not needed for the transfer of a methyl group from betaine to form choline, but it was essential with dietary choline or its precursors for prevention of perosis.—E. M. Cruickshank.

MARCH, B. E. and BIELY, J. (with BURDETT, M. and MOREL, F.) Fat studies in poultry. 3. Folic acid and fat tolerance in the chick. *Poultry Sci.*, 1955, **34**, 39-44. [Poultry Nutrition Lab., Univ. British Columbia, Vancouver.]

Chicks were given for 5 weeks a diet lacking in, or supplemented with, folic acid, with additions of up to 6 per cent. of fresh or strongly heated herring

N.A. and L., October 1955

oil or of cottonseed oil. When the diet was lacking in folic acid growth was not affected by inclusion of 3 per cent. of fresh or treated oil, but in some experiments it was depressed by inclusion of 5 or 6 per cent., particularly when the oil had been heated. The depression was completely prevented by a supplement of folic acid. The

results showed that a high proportion of fat in the diet increased the chick's requirement for folic acid. Efficiency of feed utilisation was decreased by adding oil when the diet lacked folic acid, but was increased by adding oil when folic acid was given. Folic acid had no lipotropic effect and did not increase fat absorption.—E. M. Cruickshank.

MASCHERPA, P. Alcune caratteristiche di un composto di cobalto ottenuto per sintesi, avente attività vitaminica B₁₂. [Characteristics of a compound of cobalt obtained by synthesis and having vitamin B₁₂ activity.] *Bol. Soc. ital. Biol. sper.*, 1953, **29**, 1511-1514. [Ist. Farmacol., Univ. Pavia.]

A compound of cobalt with ribonucleic acid was obtained by a special technique. It had a molecular weight of 1345, was very slightly soluble in water, and contained 0.42 per cent. Co estimated polarographically. The empirical formula was (C₂₈H₄₈N₁₅O₂₃P₄)_nCo. Its maximum absorption was at 306 mμ., its colour was reddish and its growth-promoting effect for *Bacterium coli* 113/3 was modest. It had anti-anaemic potency for the hypochromic anaemia of rats fed on a milk diet, and for the hyperchromic, macrocytic anaemia of

rats given acetylcholine bromide. (See also Abst. 3581, Vol. 25.)—E. M. Hume.

SHENOY, K. G. and RAMASARMA, G. B. Iron as a stabilizer of vitamin B₁₂ activity in liver extracts and the nature of so-called alkali-stable factor. *Arch. Biochem. Biophys.*, 1955, **55**, 293-295. [Res. and Control Div., Raptakos, Brett and Co., Ltd., Bombay, India.]

Vitamin B₁₂ in liver extracts was protected from destruction by heat at pH 10 by addition of Fe. Aqueous solutions of crystalline vitamins B₁₂ and B_{12b} were not protected by ferric chloride. Crystalline vitamins added to a liver extract were destroyed by heating at pH 10 but could be stabilised by adding ferric chloride. The bearing of the results on tests for vitamin B₁₂ activity before and after heat treatment is considered.

BOCCHIOTTI, S. Sulla possibilità di ottenere un estratto epatico ad alto contenuto in vit. B₁₂ mediante il metodo della pressione frazionata. [Possibility of obtaining a liver extract with high vitamin B₁₂ content by fractional pressure.] *Bol. Soc. ital. Biol. sper.*, 1953, 29, 1522-1524. [Inst. Farmacol., Univ. Pavia.]

A portion of 100 g. fresh calves' liver was subjected in a micro-press to 4 successive degrees of pressure, 150, 400, 600 and 800 atmospheres. The 4 fractions obtained were heated at pH 6.5 and 80° C. for 90 min. Vitamin B₁₂ was estimated with *Bacterium coli* 113/3 in the original material and in the fractions. In 8 experiments, the first fraction, consisting of between 50 and 60 g. of the material, and the last, of from 7 to 9 g., contained no vitamin B₁₂. The second fraction of from 12 to 16 g. contained from 46 to 50 µg. and the third of from 7 to 10 g. contained from 12 to 17 µg. The amount in the whole liver sample was from 67 to 72 µg. The 2 fractions obtained between 150 and 600 atmospheres were purified with the ultra-centrifuge and columns of Permutit, and yielded a clear brown liquid with 30 µg. vitamin B₁₂ per ml.—E. M. Hume.

JANIČKI, J. and PAWEKIEWICZ, J. Wytwarzanie nowej witaminy (vitamin) grupy B₁₂ przez bakterie kwasu propionowego. [Formation of new vitamins of the B₁₂ group by propionic acid bacteria.]

PAWEKIEWICZ, J. Prekursory biosyntezy witamin grupy B₁₂. [Precursors in the biosynthesis of B₁₂ vitamins.] *Acta biochim. polon.*, 1955, 1, 307-312; 313-326. [Inst. Biochem., Rolnej WSR, Poznan.] English and Russian summaries.

In addition to small amounts of vitamin B₁₂, *Propionibacterium shermani* produced another vitamin named vitamin B_{12ap}. It has not yet been crystallised. It did not contain the benzimidazole group, and formed in acid solution a stable complex containing 2 cyanide groups. It was inactive for *Euglena gracilis*, but from twice to four times more active than vitamin B₁₂ for *Bacterium coli*.

When the *Propionibacterium* was grown on a medium containing 5:6-dimethylbenzimidazole it produced vitamin B₁₂ instead of vitamin B_{12ap}. An analogous procedure resulted in the production of a vitamin B₁₂ derivative, 5(6)-methylbenzimidazole cyanocobalamin, when the culture medium contained 5-methylbenzimidazole. The substance was active for *Bact. coli* and *Euglena gracilis*. Other methyl- and dimethyl-benzimidazoles were tested as precursors of B₁₂ vitamins but proved inactive. *Strep. griseus* did not use 5:6-dimethylbenzimidazole for increased synthesis of vitamin B₁₂. (From summaries.)—E. M. Hume.

SAHASHI, Y., IWAMOTO, K. and HAYASHI, J. Biosynthesis of vitamin B₁₂ in domestic ducks. *J. Vitaminol., Japan*, 1954, 1, No. 1, 39-42. [Lab. Biochem., Fac. Agric., Univ. Tokyo, Hongo.]

Actinomycetes found in the digestive tract of ducks were shown to be capable of synthesising vitamin B₁₂. Other organisms similarly isolated had little ability to do so. The highest concentration of vitamin B₁₂ was in the caecum and the greatest total amount in the small intestine. When radio-active ⁶⁰Co was given to ducks, vitamin B₁₂ containing ⁶⁰Co was found in the digestive tract, especially in the small intestine and liver.

DALE, F. H. Ability of the bobwhite to grow and reproduce without a dietary source of vitamin B₁₂. *Science*, 1955, 121, 675-676. [U.S. Fish and Wildlife Serv., Laurel, Md.]

Three groups of 30 bobwhite quail chicks, 2 weeks old, were reared in wire-floored pens. They received the basal mash containing, per cent., soya bean meal 42, yellow maize meal 41, wheat middlings 10, lucerne meal 4, CaCO₃ 2, NaCl (with added iodide and manganese sulphate) 0.5, and vitamin A and D oil 0.5; to each 100 kg. of mash were added 40 g. choline chloride, 40 mg. folic acid, 800 mg. riboflavin and 800 mg. Ca pantothenate. One group received no further supplement, one received 15 µg. vitamin B₁₂ per kg. diet, and one received 20 g. dried soil per kg. diet. There was no significant difference in the growth of the 3 groups. From each group 4 pairs were placed in breeding pens with the same diets. For the 3 treatments, respectively, the mean fertility of the eggs was 81, 83 and 80 per cent.; and of the fertile eggs the hatching rate was 70, 75 and 64 per cent. Eggs were taken for analysis and the mean vitamin B₁₂ value was 22, 42 and 29 µg. per g. yolk.

It is concluded that, since the birds were living in conditions where coprophagy was almost eliminated, the bobwhite quail must be able to utilise vitamin B₁₂ synthesised in the digestive tract.

WOOLLEY, D. W. A further study of the apparent synthesis of vitamin B₁₂ by mammary cancers of mice. *Proc. Nat. Acad. Sci., Washington*, 1955, 41, 111-118. [Rockefeller Inst. Med. Res., New York.]

After a careful study of microbiological methods for estimating vitamin B₁₂, the chrysomonad method of Hutner *et al.* (*Ann. N.Y. Acad. Sci.*, 1953,

N.A. and R., October 1955

56, 852) proved to be the most satisfactory. With that method it was found that the concentration of vitamin B₁₂ per g. bodyweight was 17 $\mu\mu\text{g}$. in mice with mammary tumours and 9 $\mu\mu\text{g}$. in mice with no tumour. All the animals received a diet deficient in vitamin B₁₂, based on cottonseed meal as source of protein. One transplanted cancer strain gave evidence of synthesis of vitamin B₁₂, but another caused active destruction of the vitamin. The findings are discussed in relation to the influence of tumour tissue on the body supply of vitamin B₁₂.—A. M. Copping.

CRESSERI, A. Observations on vitamin B₁₂-binding factor from hog gastric mucosa. *Experientia*, 1955, **11**, 111-112. [Biol. Lab., Ist. Carlo Erba Ricerche Terap., Milan.] Italian summary.

A highly concentrated preparation from pig gastric mucosa was further analysed by continuous paper electrophoresis followed by extraction and fractional precipitation from phenol-ethanol mixtures. The highest binding activity for vitamin B₁₂ was in a fraction precipitated with from 50 to 60 per cent. ethanol. The fraction contained, per cent., nitrogen 8.2, hexosamines 17.1, reducing sugars 18.3, non-glucosamine polysaccharides 21.6. Its binding capacity was 22-23 μg . vitamin B₁₂ per mg.—A. M. Copping.

ROSENTHAL, H. L. and HAMPTON, J. K. (Jr.) The absorption of cyanocobalamin (vitamin B₁₂) from the gastrointestinal tract of dogs. *J. Nutrition*, 1955, **56**, 67-82. [Dept. Med., Sch. Med., Tulane Univ., New Orleans, La.]

Absorption of vitamin B₁₂ was studied in dogs fasted from a normal diet for from 16 to 24 hr. before experiment, performed under light nembutal anaesthesia. A polythene cannula was inserted into the portal vein and solutions of crystalline cyanocobalamin were placed in the stomach or duodenum by a tube passed through the oesophagus. In some experiments the vitamin B₁₂ was placed in segments of the duodenum which were tied off, and in others it was injected intravenously. Blood samples were taken from the portal and jugular veins and urine was withdrawn by catheter.

Ligation at the duodenal cap decreased absorption of vitamin B₁₂ from the stomach. During absorption the amount in the portal blood was always greater than in the peripheral blood. Considerable absorption took place from the segments of the duodenum that had been tied off. In the post-absorptive state the amount of vitamin B₁₂ in the portal and peripheral blood was much the same. The amount of vitamin B₁₂ in the urine was very small when it was given by mouth, but large when it was given intravenously. If saline was given by tube to a dog that had been operated on there was no change in the vitamin B₁₂ of plasma or urine.—A. M. Copping.

WILSON, H. E. and PITNEY, W. R. (with LABAW, E. and LONG, M.) Serum concentrations of vitamin B₁₂ in normal and nutritionally deficient monkeys. *J. Lab. Clin. Med.*, 1955, **45**, 590-598. [Dept. Med., Northwestern Univ. Med. Sch., Chicago, Ill.]

Vitamin B₁₂ was estimated with *Euglena gracilis* in serum from monkeys maintained on normal diets, on purified diets lacking in some vitamins, and on homogenised cow's milk in which ascorbic acid was

destroyed with copper sulphate. In 17 young animals on normal diet the value for vitamin B₁₂ in the serum ranged from 50 to 234 $\mu\mu\text{g}$. per ml. with a mean of 120 $\mu\mu\text{g}$. The values were slightly lower than those found in 56 specimens of normal human serum. When folic acid was excluded from purified diets the vitamin B₁₂ value for the serum ranged from 25 to 54 $\mu\mu\text{g}$. per ml. The increase was slight when folic acid was added and much greater when vitamin B₁₂ was given up to 10 μg . daily. Intravenous administration of vitamin B₁₂ produced high values in the serum. Ascorbic acid deficiency was associated with low values, but monkeys having the homogenised milk, which contained appreciable amounts of vitamin B₁₂, had fairly high serum values. Estimation of vitamin B₁₂ in the faeces in some experiments showed that considerable amounts were excreted whether the serum concentration was high or low. In severe folic acid deficiency the vitamin B₁₂ value in the serum was normal; it rose during recovery, possibly because of an increase in absorption. In monkeys receiving synthetic diets after long periods on milk diet vitamin B₁₂ remained high in the serum.

JAFFÉ, W. G. Reproducción, lactacia, crecimiento y niveles de glutación en ratones con una dosis baja de vitamina B₁₂. [Reproduction, lactation, growth and level of glutathione in mice on a diet low in vitamin B₁₂.] *Arch. venezol. Nutricion*, 1954, 5, 305-316. [Inst. Nac. Nutric.] English and German summaries.

Groups of mice received for several generations a commercial rat diet with about 30 μg . vitamin B₁₂ per kg. or a basal diet, containing per cent. soya flour 46, maize 46, vegetable oil 5 and minerals 2, with added vitamins A, D, E and the B complex except vitamin B₁₂; it contained less than 0.1 μg . vitamin B₁₂ per 100 g. Some groups received a supplement of 3 μg . vitamin B₁₂ per kg. diet all the time or only during lactation. Litters were reduced to 6 animals and weaned at 28 days.

Only with the basal diet without supplement was the number of young born in a litter significantly less than for the group having the commercial diet. The age at which females had their first litters was greatest, and the mean number and weight of the young at 28 days were least, on the basal diet alone. An intake of 3 μg . vitamin B₁₂ per kg. diet sufficed for normal reproduction. In young mice having the basal diet alone growth was slower, being less in the fourth and fifth weeks of age and greater in the sixth and seventh weeks than in mice given vitamin B₁₂. With none of the diets was there a significant difference in the glutathione content of the blood or liver in adult mice.—D. Duncan.

VERLY, W. G. and CATHEY, W. J. The influence of vitamin B₁₂ on the biosynthesis of the methyl group of choline from methanol. *J. Biol. Chem.*, 1955, 213, 621-624. [Dept. Biochem., Cornell Univ. Med. Coll., New York.]

Rats were given purified diets deficient in vitamin B₁₂ only or in vitamin B₁₂ and folic acid. When deficiency signs appeared an injection of methanol labelled with ¹⁴C was given. The rats were killed 8 hr. later and choline was isolated from the carcasses as chloroplatinate, degraded to trimethylamine and oxidised to carbonate in which ¹⁴C could be estimated. Rats deficient in vitamin B₁₂ incorporated less ¹⁴C into choline than rats treated with vitamin B₁₂. These deficient in both vitamin B₁₂ and folic acid showed a still lower uptake of ¹⁴C into the methyl group of choline.

SHILS, M. E., DE GIOVANNI, R. and STEWART, W. B. Fatty liver of portal type: effects of choline, methionine, and vitamin B₁₂. *J. Nutrition*, 1955, 56, 95-106. [Sch. Pub. Health, Columbia Univ., New York.]

Young rats having diets containing 74 per cent. maize meal or ground white rice or cassava flour and 17 per cent. of fat developed fatty livers with accumulation of lipid in the portal areas. Treatment with vitamin B₁₂ or choline had no effect on accumulation of fat in the liver. Inclusion of parent per cent. DL-methionine in the diet failed to increase fatty liver and, in male rats, appeared to increase the accumulation of fat. Larger amounts of methionine, 1.0, 1.5 or 2.0 per cent., decreased fat accumulation but had a bad effect on methods. The fatty deposits in the portal areas showed an analysis iodine values and cholesterol *A.*, 1953,

N.A. and R., October 1955

like those in the fatty livers induced by a choline-deficient diet with casein as source of protein.

CHANG, I. and JOHNSON, B. C. **The effect of vitamin B₁₂ on some aspects of glycine metabolism.** *Arch. Biochem. Biophys.*, 1955, **55**, 151-156. [Div. Animal Nutrit., Univ. Illinois, Urbana.]

A previous study (Abst. 3590, Vol. 25), showed that glycine protected pigs from choline deficiency only if adequate vitamin B₁₂ was present in the diet. Of 2 pigs from the previous study, maintained on a diet deficient in vitamin B₁₂ and choline, one was given vitamin B₁₂. After 36 days of experiment, when the one deprived of vitamin B₁₂ was showing severe signs of deficiency, both were given glycine marked with ¹⁴C in the α -carbon atom. They were killed 4 hr. later and the livers were quickly frozen and kept at -10° C. until they were analysed. Urine was collected during the 4 hr. after administration of glycine, and serine, choline and aminoethanol were estimated. Serine and choline were estimated also in the liver and the distribution of ¹⁴C was determined. Deprivation of vitamin B₁₂ decreased the incorporation of the α -C of glycine into the methyl group of choline but had no effect on the formation of serine or aminoethanol.—A. M. Copping.

per 1 CH, E. M., SWIFT, H. and SCHWEIGERT, B. S. **addes Liver nucleoproteins in vitamin B₁₂ deficiency.** *transic Proc. Soc. Exp. Biol. Med.*, 1955, **88**, 637-640. *mated* Whitman Lab., Dept. Biochem., Univ. filtrate neago, Ill.]

binding effect of vitamin B₁₂ deprivation on the intrinsic of deoxyribonucleic acid, ribonucleic acid and 198 topoplasmic protein in the liver was studied

cytochemically in rats having for 6 weeks a diet of maize and soya bean oil with iodinated casein and with or without vitamin B₁₂. A third group of rats had no vitamin B₁₂ for 4 weeks and then a dose of 50 μ g. per kg. diet for 2 weeks. There was no difference in the concentration of total protein in the liver of the 3 groups, but in deficient rats there was an increase in the amount per cell associated with the increased cytoplasmic volume. In deficient rats there was a decreased concentration of nucleic acid but an increase in amount per cell. There was no change in the amount of deoxyribonucleic acid per single tetraploid nucleus, but when the amount was calculated on the basis of the frequency of polyploid classes there was a small decrease associated with a higher frequency of diploid nuclei in deficient rats.—A. M. Copping.

PROSIEGEL, R. **Der Einfluss von Leberschutzstoffen auf den Gehalt der tetrachlorkohlenstoffgeschädigten Rattenleber an Pyridincofermenten (DPN/DPNH₂).** [The effect of liver-protective substances on the content of pyridine coenzymes in the liver of rats poisoned with carbon tetrachloride.] *Ztschr. ges. exp. Med.*, 1954-55, **125**, 323-330. [Med. Poliklin., Univ. Munich.]

Diphosphopyridine nucleotide and its dihydroform were estimated by the method of Helmreich *et al.* (*Hoppe-Seyler's Ztschr.*, 1954, **297**, 2) in the liver of normal adult rats and of rats having CCl₄ for from 3 to 7 days. The poisoned livers showed a lowered content of dihydrodiphosphopyridine nucleotide which could be prevented if vitamin B₁₂ or a liver hydrolysate was given at the same time as CCl₄; even in severely toxic rats administration of vitamin B₁₂ or liver extract exercised a favourable effect on the concentration of the coenzyme. The protective effect of vitamin B₁₂ or liver hydrolysate against carbon tetrachloride poisoning is discussed.—A. M. Copping.

The addition of vitamin B₁₂ and folic acid to the medium in which fibroblasts from chick heart were grown prevented the accumulation of lipid globules

in the cytoplasm and apparently stimulated growth. Freshly excised tissue and vitamin-treated cultures were almost free from neutral fat as shown by the ratio of fatty acids to phospholipin P; in degenerating cultures, in the absence of added vitamins, the ratio increased rapidly.

PENHOS, J. C. and FOGLIA, V. G. **Renforcement de l'action de l'hormone de croissance par l'acide folique et la cobalamine. [Enhancement of the action of growth hormone by folic acid and cobalamin.]** *C.R. Soc. Biol.*, 1954, **248**, 2113-2115.

In hypophysectomized rats weighing from 104 to 110 g. administration of growth hormone (Somatropin, Armour) produced an increase in bodyweight and in the weight of the liver, kidneys and uterus. The effect was enhanced by administration of folic acid and less significantly by cobalamin, neither of which had an effect when given without growth hormone. Folic acid increased also the growth in length of the femur and tibia which was induced by the hormone. Cobalamin but not folic acid acted in the same way on the weight of the thymus gland. Both the hormone and folic acid were required to increase the weight of the ovary. They had no effect on the thyroid gland. On the adrenal glands the hormone had

a slight effect which was not significantly greater with folic acid or cobalamin.—A. Hepburn.

MÜCKE, D. and MORCZEK, A. **Der Schutzeffekt von Vitamin B₁₂ und Folsäure auf das Blutbild bei Röntgenbestrahlung. [The protective effect of vitamin B₁₂ and folic acid on the blood picture after exposure to X-rays.]** *Naturwissenschaften*, 1954, **41**, 579-580. [Physiol. Chem. Inst., Univ. Leipzig.]

Seven groups of 8 male guineapigs weighing about 400 g. were given a total body exposure to X-rays of 250 r. Of one group, half were given, daily for 7 days, 50 and half 100 µg. folic acid by intramuscular injection before exposure; a second group was similarly treated with 50 or 100 × 10⁻⁹ g. vitamin B₁₂, and a third with both vitamins; 3 other groups had the same treatments after exposure, and the 7th group was untreated.

In guineapigs treated with folic acid the red cell count did not fall as low as, and returned to normal earlier than, in untreated animals. Treatment before exposure was more effective than treatment after. The white cell count behaved in the same way. Vitamin B₁₂ had a similar but smaller effect. No advantage resulted from combination of the 2 vitamins. The findings will be published in more detail in *Strahlentherapie*.

GARD, D. I., TERRILL, S. W. and BECKER, D. E. **Effects of the addition of dehydrated alfalfa meal, fish solubles and a "vitamin B₁₃" concentrate to a purified diet for sows.** *J. Animal Sci.*, 1955, **14**, 562-572. [Illinois Agric. Exp. Stat.]

In 2 experiments the purified diet consisted of, per cent., maize starch 63.9, dextrose 10, maize oil 2, woodflock 3 and alpha-protein 16, with DL-methionine, minerals and vitamins; in the third, Drackett protein 17.2 replaced the alpha-protein [sources of these not specified]. In all 3 trials, groups were given 10 per cent. dehydrated alfalfa in addition to the purified diet, and in the

N.A. and R., October 1955

second experiment there were also groups getting 3 per cent. menhaden fish solubles or "vitamin B₁₃" in a concentrate extracted from maize distiller's solubles. Gestation performance was judged by the weight, number and strength of the piglets at birth, and lactation by the number of pigs weaned, amount of feed per lb. gain of litter and sow, and individual and litter weights.

The alfalfa supplement had no consistent effect on gestation or lactation. With its conception rates were better than without and fewer services per conception were required after it had been given for 233 days; 88 per cent. of the sows getting the supplement but only 55 per cent. of those without it were able to rear their litters to weaning. After the experiment the sows were slaughtered. Examination of the reproductive tract showed no disorder, and there was no difference between treatments in their effect on rate of ovulation.

Menhaden fish solubles and "vitamin B₁₃" did not appear to have any beneficial effect on gestation or lactation. It was considered that the purified diets used in the experiments were suitable for use in studies of gestation and lactation in sows.

TITUS, H. W., BRUMBAUGH, J. H. and MEHRING, A. L. (Jr.) Evaluation of the effect of additions of vitamin B₁₂, DL-methionine, and procaine penicillin, singly and in combination, to corn-soybean diets for young growing chicks. *Poultry Sci.*, 1955, 34, 167-177. [Lime Crest Res. Lab., Limestone Products Corp. of America, Newton, N.J.]

The results of 2 experiments were analysed by a new method of evaluating the factors in a 2³ factorial nutrition experiment. In the first test, the diet of the chicks contained 46 per cent. of soya bean meal, and in the second, 35 per cent. Addition of vitamin B₁₂ increased the efficiency of feed utilisation and the gain in weight of both sexes. The effect was at its maximum at 4 weeks of age. Weight declined during the next 6 weeks, the decrease being much greater in female chicks. Addition of DL-methionine, purified or of commercial grade, did not improve efficiency of feed utilisation or stimulate growth; in the females it appeared to depress growth. Procaine penicillin, 2.5 mg. per lb. feed, increased the growth of both sexes, but 1.25 mg. was less effective; there was no consistent influence on feed utilisation.

WELCH, B. E. and COUCH, J. R. Homocystine, vitamin B₁₂, choline, and methionine in the nutrition of the laying fowl. *Poultry Sci.*, 1955, 34, 217-222. [Dept. Poultry Husb., Texas Agric. Exp. Stat., College Station.]

Vol. 25, No. 4

Hens, which in the pre-experimental period received a ration adequate in vitamin B₁₂ and methionine, were given a basal diet lacking in vitamin B₁₂ and containing 0.26 per cent. methionine and 0.145 per cent. choline. The diet was supplemented with vitamin B₁₂, homocystine, methionine and choline, separately and in different combinations. The supply of methionine was found to be the chief limiting factor in the basal diet. Egg production and the results of blood analysis showed that the hen could form methionine through the methylation of homocystine in the presence of vitamin B₁₂, though in the conditions of the experiment the rate of synthesis was insufficient to satisfy the bird's requirement. When the basal diet was supplemented with choline and homocystine with or without vitamin B₁₂, egg production was significantly greater than with homocystine and vitamin B₁₂. When methionine was given, egg production was not influenced by addition of vitamin B₁₂ but was significantly increased by addition of choline. Since the best egg production was obtained by supplementing the basal diet with vitamin B₁₂, choline and methionine, it is considered that the laying hen requires more choline than is needed for the formation of methionine.—E. M. Cruickshank.

KERCHEER, C. J. and SMITH, S. E. The response of cobalt-deficient lambs to orally administered vitamin B₁₂. *J. Animal Sci.*, 1955, 14, 458-464. [Dept. Animal Husb., Cornell Univ., Ithaca, N.Y.]

Lambs depleted of Co by 5 months' feeding on a deficient ration were treated with 500 µg. crystalline vitamin B₁₂ daily by mouth, a feed supplement giving 100 µg. vitamin B₁₂ daily, or 100 µg. crystalline vitamin B₁₂ daily by mouth. Some lambs remained as long as possible without treatment before being injected with a total of 500 µg. vitamin B₁₂ in 2 weeks. Bodyweight and appetite were recorded; Hb was estimated, but the results were too variable to be of use.

The lambs given 500 µg. crystalline vitamin B₁₂ by mouth daily for 5 weeks gave as good a response as those treated by injection, which were considered as positive controls. Response was good also with the feed supplement, but it was later found to contain enough Co to invalidate the comparison for the purpose of this experiment. The smaller amount of crystalline vitamin B₁₂ given by mouth daily for 8 weeks was not effective.—T. D. Bell.

WHITE, E. A. Ketosis in dairy cattle: 1. The role of cobalt and the significance of vitamin B₁₂ in this metabolic disturbance. *Vet. Med.*,

1955, 50, 199-202. [Sch. Vet. Med., Michigan State Coll., East Lansing.]

Faulty rumen function and adrenal insufficiency are discussed as causes of primary ketosis. Successful treatment with dextrose or vitamin B₁₂ by vein and cobalt by mouth sulphate is reported. The success of the method seemed to justify it. It is suggested that the additional vitamin B₁₂ formed in the rumen may stimulate the adrenal glands.

HASHIMOTO, Y. Vitamin B₁₂ in marine and freshwater algae. *J. Vitaminol., Japan*, 1954, 1,

49-54. [Lab. Fish. Chem., Fac. Agric., Tokyo Univ., Hongo.]

The vitamin B₁₂ content of edible seaweeds, estimated with *Euglena gracilis*, ranged from 15 to 20 µg. per 100 g. air-dried *usakusanori*, *Porphyra tenera*. The alga was effective as a source of vitamin B₁₂ for chicks. About 30 other species of seaweed were studied and the vitamin B₁₂ values were from 0.1 to 4.0 µg. per 100 g. wet material. Some samples of zooplankton and pond muds also contained considerable amounts of vitamin B₁₂.

GANDER, J. E. and SCHULTZE, M. O. Concerning the alleged occurrence of an "animal protein factor" required for the survival of young rats. 1. Studies with unpurified rations.

SCHULTZE, M. O. 2. Reproduction of rats fed protein-free amino acid rations. *J. Nutrition*, 1955, 55, 543-557; 559-575. [Dept. Agric. Biochem., Univ. Minnesota, Inst. Agric., St. Paul.]

1. Diets, based on cereals and exhaustively extracted casein or on sucrose and amino-acid mixtures, were given to rats for several generations in an attempt to demonstrate the need for the

water-soluble, heat-stable animal-protein factor associated with crude casein, not identifiable with any of the known B vitamins, postulated by Piccioni *et al.* (Abst. 3530, Vol. 21) as protecting against poor reproductive performance and promoting the survival of rats. While the syndrome described occurred with some diets, apparently minor changes in the ration, not associated with casein or other animal protein, sufficed to prevent its appearance. The findings remain unexplained.

2. Amino-acid mixtures known to be satisfactory for growth in normal animals were inadequate during reproduction and lactation.—C. Warner.

VITAMIN C (ASCORBIC ACID)

4990

BOGDAŃSKA, H., DESPERAK-SECOMSKA, B. and SZCZYGIŁOWA, M. Badania nad metodą enzymatyczno-mikrobiologiczną oznaczania kwasu askorbinowego i dehydroaskorbinowego w obecności reduktorów. [Studies on the enzymic-microbiological method of estimating ascorbic acid and dehydroascorbic acid in the presence of reducing agents.] *Rocz. Państwowego Zakł. Hig.*, 1954, 5, 327-348. Russian and English summaries.

The method of Stewart and Sharp (Abst. 2309, Vol. 15), in which ascorbic acid and interfering reducing substances are oxidised by ascorbic acid oxidase and the resulting dehydroascorbic acid is specifically reduced again by bacteria, was studied. To obtain results with not more than 3 per cent. error allowance had to be made for the failure of some of the interfering reducing substances to be oxidised and for the observation by Mapson and Ingram (Abst. 1915, Vol. 21) that dehydroascorbic acid is not completely reduced to ascorbic acid by bacteria. (From summary.)—A. Hepburn.

SCHMIDT, H. and STAUDINGER, H. Papierchromatographische Bestimmung von Ascorbinsäure und Dehydroascorbinsäure. [Estimation of ascorbic acid and dehydroascorbic acid by paper chromatography.] *Biochem. Ztschr.*, 1955, 326, 343-349. [Zentrallab., Städt. Krankenhaus, Mannheim.]

The application of paper chromatography to the estimation of ascorbic and dehydroascorbic acid was found to be satisfactory when oxalic acid solutions were employed. With tissue extracts ascorbic acid could be estimated in an atmosphere of CO₂, and total ascorbic acid in one of H₂S. The difference between the two gave the dehydroascorbic acid content. The validity of the method was demonstrated by good recoveries when known amounts of ascorbic or dehydroascorbic acid were added to tissue preparations.—A. M. Copping.

The syndrome of vitamin C deficiency is discussed. It is concluded that some tissues receive priority in vitamin C supplies, and that severe nonspecific "collagenosis", produced in advanced deficiency, may be irreversible.—D. Duncan.

4996

ICHIHARA, K. Ascorbic acid and protein metabolism. *J. Vitamins, Japan*, 1954, 1, 55-84. [Dept. Biochem., Osaka Univ. Med. Sch., Nakanoshima.]

Results previously reported in Japanese by a number of observers are summarised. From experiments with guineapigs it was established that onset of scurvy was hastened by a simultaneous deficiency of tryptophan, and delayed if anthranilic

acid was added to the diet lacking in ascorbic acid. From tests *in vitro* with liver homogenates, it was concluded that 5-hydroxyanthranilic acid was the active form of anthranilic acid. A diet containing 40 per cent. casein caused more rapid onset of scurvy than one lower in protein. Administration of tyrosine, cystine and histidine caused a rapid decrease in the ascorbic acid content of the guineapig's liver. Homogentisic acid added to the diet prolonged survival of scorbutic animals. Simultaneous injection of butyric acid and tyrosine into guineapigs deprived of vitamin C caused excretion of benzoquinoneacetic acid in the urine and appearance of cataract.

By chemical methods of estimation relationships between ascorbic acid and diketogulonic acid were investigated. It is suggested that in metabolic reactions between ascorbic acid and amino-acids, diketogulonic acid is an intermediary metabolite.

NADEL, E. M., MULAY, A. S. and SASLAW, L. D. On the failure of glycogen deposition in the livers of scorbutic guinea pigs. *Endocrinology*, 1955, 56, 584-589. [Lab. Pathol., Nat. Cancer Inst., Nat. Inst. Health, Bethesda, Md.]

Six hr. after intraperitoneal injection of fructose, glucose or alanine the livers of scorbutic guineapigs contained less glycogen than those of starved or normal animals treated in the same way. In all 3 groups the deposition of glycogen was less with alanine than with glucose or fructose, which were equally effective. The starved group, which lost about as much weight as the scorbutic group, deposited glycogen normally after injection. Glycogen increased after the injection of ascorbic acid in starved, but not in normal or scorbutic, guineapigs. A. Hepburn.

BANERJEE, S. and GHOSH, P. K. Effect of scurvy on hexokinase activity of tissues of guinea pigs. *Proc. Soc. Exp. Biol. Med.*, 1955, 88, 415-416. [Dept. Physiol., Presidency Coll., Calcutta.]

The hexokinase activity of skeletal muscle and liver from scorbutic guineapigs was significantly less than in pair-fed, non-deprived animals; in the kidneys it was greater and in the pancreas there was no difference.—A. Hepburn.

5000

BERNARDINI, A. and CIMINO, G. Il comportamento delle proteine plasmatiche di fronte al calore nel corso dell'avitaminosi C. [The effect of heat on plasma proteins in the course of vitamin C depletion.] *Bol. Soc. ital. Biol. sper.*, 1953, 29, 1344-1346. [Ist. Patol., Univ. Catania.]

Twenty guineapigs weighing about 500 g., after a preliminary period on a diet rich in cabbage, were given for 30 days a scorbutogenic diet in which vitamin C had been destroyed by heating. Half of them received 1 mg. ascorbic acid daily. At the end of the experiment they were killed and ascorbic acid was estimated in the liver and adrenal glands. At intervals of 10 days during the experiment specimens of the diluted blood plasma were exposed to temperatures of 45°, 50° and 55° C., and the light transmission was measured with filter S53 in the Pulfrich photometer. In the plasma heated at 45° C. the non-deprived animals showed no turbidity, and the deprived ones only a small degree. At 50° and 55° C. the turbidity was progressively more, and was greater in the deprived guineapigs. The liver and adrenal glands of the non-deprived guineapigs contained, respectively, 0.087 and 0.284 mg. ascorbic acid per g. tissue; in the organs of the deprived guineapigs no trace could be found.—E. M. Hume.

SOKOLOFF, B., EDDY, W. H., BEAUMONT, J., WILLIAMS, J. and POWELLA, R. Effect of ascorbic acid and glucoascorbic acid on nucleic acids in tumor tissue. *Cancer Res.*, 1955, 15, 147-150. [A. P. Cook Mem. Cancer Lab., Florida Southern Coll., Lakeland.]

In guineapigs fed on a scorbutogenic diet the amount of deoxyribonucleic acid in fibrosarcoma tissue and in the nuclei of the tumour cells was reduced. Excess of ascorbic acid tended to increase the amount of deoxyribonucleic acid in the total tissue but had no significant effect on the amount in the nuclei. In rats fed on a scorbuto-

genic diet the amount of total and nuclear deoxyribonucleic acid in Crocker carcinoma tissue was reduced, and was further decreased when a low level of ascorbic acid was produced in the tissues by giving glucoascorbic acid. In guineapigs the deoxyribonucleic acid content of the tumours was not affected by giving glucoascorbic acid. The decrease in nuclear deoxyribonucleic acid was greater in guineapigs than in rats. The amount of total ribonucleic acid in tumour tissue from either species was not significantly altered.—A. Hepburn.

5003

BERNARDINI, A. and CALTABIANO, S. L'azione dei raggi roentgen sul metabolismo dell'acido ascorbico. [Action of X-rays on ascorbic acid metabolism.] *Bol. Soc. ital. Biol. sper.*, 1953, 29, 1869-1872. [Ist. Patol., Univ. Catania.]

Groups of 10 rats weighing about 160 g. were maintained on a scorbutogenic diet. One group was exposed to X-rays, 350 r., over the whole body. Ascorbic acid was estimated by indophenol titration in the urine beforehand and 18 hr., 40 hr. and 15 days later, and with methylene blue in the adrenal glands, liver and spleen when the rats were killed 15 days after exposure. In the organs of the treated rats the mean content of ascorbic acid was from 57 to 70 per cent. less than in the untreated. In the urine of the treated rats, the amount of ascorbic acid increased progressively, and after 15 days was more than 10 times greater than before treatment.—E. M. Hume.

5004

NIGEON-DUREUIL, M. and RATSIMAMANGA, A. R. Preuves biologiques de la déviation du métabolisme du système enzymatique de la surrénale scorbutique. [Biological proof of a change in the metabolism of the enzyme system in scorbutic adrenal glands.] *C.R. Soc. Biol.*, 1955, 149, 21-24. [Lab. Physiol. Vitamines, Fac. Méd., C.N.R.S., Paris.]

Of 14 guineapigs weighing from 150 to 350 g., given for 30 days a diet deficient in vitamin C, half received 100 mg. ascorbic acid daily. They were all killed and a saline extract of the adrenal glands was incubated with deoxycorticosterone. The resulting material was extracted successively with ethanol, acetone, chloroform and methanol, and the extracts were chromatographed on paper. The substances obtained were eluted and tested on adrenalectomised rats for their protective value against exposure to cold.

Substances from the adrenal glands of normal guineapigs prolonged the life of adrenalectomised rats exposed to cold, but substances from the adrenal glands of the scorbutic guineapigs were toxic and reduced the survival time.

It is concluded that in scurvy the metabolism of deoxycorticosterone in the adrenal glands is changed.—D. Duncan.

5005

NIGEON-DUREUIL, M., RABINOWICZ, M., RAHAND-RAHA, T. and RATSIMAMANGA, A. R. Déviation possible du métabolisme des corticostéroïdes au niveau de la surrénale au cours du scorbut expérimental. BURSTEIN, S., DORFMAN, R. I. and NADEL, E. M. Corticosteroids in the urine of normal and scorbutic guinea pigs: isolation and quantitative determination. *J. Biol. Chem.*, 1955, **213**, 597-608. [Worcester Found. Exp. Biol., Shrewsbury, Mass.]

Urine from scorbutic and normal guineapigs contained cortisol, 6 β -hydroxycortisol and an unknown steroid previously isolated from urine of normal guineapigs that had been given cortisol by mouth. Scorbutic guineapigs excreted the first 2 steroids in concentrations 300 and 80 per cent. above the values for the normal animals; the concentration of unknown steroid was unchanged. Adrenocorticotrophic hormone did not increase the urinary steroids of scorbutic guineapigs.—A. Hepburn.

5007

OERTEL, G. and HEIN, H. Trennung der 17-Ketosteroid im Harn skorbütischer Meerschweinchen. [Separation of 17-ketosteroids in the urine of scorbutic guineapigs.] *Hoppe-Seyler's Ztschr.*, 1954, **297**, 249-253. [Lab. Firma Byk-Gulden-Lomberg, Chem. Fabrik. G.m.b.H., Constance.]

By paper chromatography 25 fractions were separated from the ketosteroid components of guineapig urine. Normal guineapigs excreted on the average 230 μ g. ketosteroids daily. After 10 days on a diet lacking in vitamin C the mean value was 673 μ g. The distribution of the ketosteroids in the different chromatographic fractions was very different in normal and scorbutic animals. The change in ketosteroid excretion in vitamin C deficiency was considered to be connected with changes in adrenal cortical function.

BOOKER, W. M., DaCOSTA, F. M., TUREMAN, J. R., FROIX, C. and JONES, W. The relation of ascorbic acid to adrenocortical function during cold stress. *Endocrinology*, 1955, **56**, 413-419. [Dept. Pharmacol., Med. Sch., Howard Univ., Washington, D.C.]

Both cortisone and ascorbic acid increased survival of intact and adrenalectomised mice subjected to cold. Ascorbic acid was more effective in intact than in adrenalectomised mice. The effect of cortisone was the same for both groups, since they both survived for 5 hr. A combination of low doses of cortisone with high doses of ascorbic acid was more effective in intact than in adrenalectomised mice, but the opposite combination was more effective with the adrenalectomised mice.

Adrenalectomised mice during stress and recovery had higher blood values for K than intact mice or mice treated with ascorbic acid. The possibility that ascorbic acid might facilitate the "handling" of K in adrenalectomised mice is suggested.

ALLEGRETTI, N., VUKADINOVIĆ, G. and RABADJICA, L. Insulin sensitivity in adrenalectomised rats treated with ascorbic acid and desoxycorticosteroneacetate (DCA). *Amer. J. Physiol.*, 1955, 180, 508-510. [*Inst. Physiol., Med. Fac., Univ. Zagreb, Yugoslavia.*]

Fasting blood sugar was estimated before, and 1, 2, 3 and 4 hr. after, administration of insulin to adrenalectomised albino rats of both sexes. In the first series of experiments the animals received insulin alone, or with ascorbic acid or subcutaneous implants of desoxycorticosterone acetate (DCA) pellets; in a second series the rats received insulin alone, or with injections of DCA in oil, with the usual laboratory food or with a salt-free diet.

Ascorbic acid did not, but DCA did, produce sensitisation to insulin action. The DCA effect was more pronounced in rats which received a normal diet than in those having the NaCl-free diet. The effects of ascorbic acid and DCA are attributed to the action of Na, DCA preserving Na in the organism, and ascorbic acid decreasing blood K and so producing a relative increase in concentration of Na.—G. F. Garton.

5015

DESMARAIS, A. L'action anti-thyroïdienne de l'acide ascorbique et de l'acétate de desoxycorticosterone (DOC). [Antithyroid action of ascorbic acid and of desoxycorticosterone acetate.] *C.R. Soc. Biol.*, 1955, 149, 214-217. [*Dept. Exp. Physiol., Fac. Méd., Laval Univ., Québec.*]

Of 6 groups of rats weighing from 105 to 175 g. one group had no operation, 4 groups had the adrenal glands and one group had the thyroid gland removed. Immediately after operation one adrenalectomised group was kept, like the intact animals, at 24° C. and given 2.5 mg. cortisone

daily and 1 per cent. NaCl to drink; 3 groups of adrenalectomised rats received the same treatment at 15° C., but rats in one of the 3 groups had in addition 150 mg. Na ascorbate daily and in another of the 3 groups 2.5 mg. desoxycorticosterone daily. The rats from which the thyroid gland had been removed were kept at 12° C. and given 3 µg. thyroxine daily and 1 per cent. sodium lactate. After 6 days the rats were killed, and the thymus, thyroid and adrenal glands not removed initially were examined.

In the rats with the adrenal glands removed, the changes in the thymus and thyroid were not statistically significant at normal temperature, but in the cold there was significant reduction in the weight of the thymus and increase in height of the thyroid epithelium; the effect on the thyroid was prevented by sodium ascorbate and both effects were prevented by desoxycorticosterone. There was no involution of the thymus in the rats with the thyroid removed, although the adrenal glands were significantly enlarged.—D. Dumeau.

5016

BOYD, T. A. S. Influence of local ascorbic acid concentration on collagenous tissue healing in the cornea. *Brit. J. Ophthalmol.*, 1955, 39, 204-214. [*Nuffield Lab. Ophthalmol., Oxford.*]

Twenty guineapigs on a diet rich in ascorbic acid had the lens removed from the left eye and a control operation made on the right eye. The cornea from the left and the right side, after injury by a standard heat treatment, healed in the significantly different mean times of 17.3 and 10.8 days. After healing, the mean ascorbic acid value for the left eye was lower than for the right in the vitreous humour, aqueous humour and cornea. The differences for the last 2 were significant. The results suggested a possible influence by the local concentration of ascorbic acid on the rate of collagen healing.—A. Hepburn.

5017

BREIDENBACH, A. W. and RAY, F. E. Effects of ascorbic acid on gastric secretion in guinea pigs. *Amer. J. Physiol.*, 1955, 180, 637-640. [*Cancer Res. Lab., Univ. Florida, Gainesville.*]

Gastric juice was collected by a gastrocutaneous fistula from normal guineapigs given an intramuscular injection of 13.8 mg. Na ascorbate per kg. daily and from those given the same injection once a week. Intraperitoneal injection of ascorbic acid in saline increased the acidity and concentration of ascorbic acid in the gastric juice of all the animals but did not affect the rate of secretion. Similar injection of saline alone had no effect. Peritoneal injection of histamine increased the acidity and rate of secretion but decreased the concentration

of ascorbic acid, probably by dilution. When histamine was not used the gastric juice from the partly deprived guineapigs had a lower acidity than juice from the non-deprived.—A. Hepburn.

GOSSSELIN, L. Action de l'acide ascorbique sur l'intestin isolé du lapin. [Effect of ascorbic acid on isolated rabbit intestine.] *Arch. internat. Pharmacodyn.*, 1955, **101**, 338-348. [Lab. Pathol., Univ. Liège.] English summary.

The effect on isolated rabbit intestine of ascorbic acid in concentrations between 4×10^{-6} and 4×10^{-3} was generally to increase both the tone and the amplitude of contractions. With successive additions contractions tended to cease. Ascorbic acid had little effect on response to acetylcholine or histamine. When added before salts of Co, Mn or Fe, ascorbic acid did not affect their action if they were in low concentration, about 1×10^{-6} ; if they were in higher concentration it had an immediate inhibitory effect.

With Cu^{++} ions the vitamin had an immediate potentiating effect, with increase of tone, which, it is suggested, may be produced by the action on —SH compounds of some substance formed during oxidation of the vitamin by copper.

OGGIONI, G. Ricerche sperimentali sull'azione antiscorbutica dell'inositol. [Experiments on the antiscorbutic action of inositol.] *Bol. Soc. ital. Biol. sper.*, 1953, **29**, 1421-1422. [Osp. Psichiat. Provinciale di Bologna in Imola.]

Vol. 25, No. 4

Six guineapigs were maintained on a diet of well dried hay, oats and water. After from 15 to 20 days, 4 were given in addition from 5 to 10 ml. daily of a 10 per cent. solution of *meso*-inositol. The 2 untreated died in from 28 to 30 days. Those given inositol recovered and survived for a couple of months. Three guineapigs given from 3 to 5 ml. of the 10 per cent. inositol solution prophylactically from the start of the experiment for more than 2 months were protected from the major signs of scurvy, though they lost weight and deteriorated slowly, with some swelling of the limbs.

DOESSBURG, J. J. Het vitamine C-gehalte van gesneden groenten. [The vitamin C content of sliced vegetables.] *Voeding*, 1955, **16**, 503-518. [Inst. Bewaring Tuinbouwprod., Wageningen.] English summary.

The effect on the vitamin C content of slicing cabbage, endive, celery, spinach and green beans some hours before cooking was studied in different conditions of temperature and moisture. Loss of vitamin C was greater in spinach than in white or yellow cabbage when stored at 2°, 10°, or 20° C. In cabbage the loss of free or bound ascorbic acid was relatively small even in sliced samples kept up to 9 hr. at 20° C. The other vegetables showed losses of ascorbic acid intermediate between those in cabbage and spinach. Loss of the vitamin appeared to be closely connected with loss of moisture from cut vegetables and with damage caused by crushing in the process of slicing or chopping. The use of moisture-proof containers did not entirely prevent the destruction of vitamin C. The ratio of ascorbic to dehydroascorbic acid decreased during storage of whole and cut vegetables. From the tests it was concluded that ordinary domestic slicing was unlikely to cause much loss of vitamin C and that with good marketing conditions vegetables for sale on the same day could be sliced without serious loss of vitamin C.

ASENJO, C. F. Ensayo biológico de vitamina C en la cereza "antillana" (*Malpighia puniceifolia* L.). [Biological estimation of vitamin C in the West Indian cherry, *Malpighia puniceifolia* L.] *Arch. venezol. Nutricion*, 1954, **5**, 317-325. [Dept. Bioquim., Esc. Med. Trop., Univ. Puerto Rico, San Juan.] English and German summaries.

Of young guineapigs given a scorbutogenic diet, 10 had no supplement and 5 groups of from 5 to 10 animals had daily 0.5 or 1 mg. ascorbic acid, or 0.05 or 0.1 ml. juice of the West Indian cherry, or 0.1 ml. of the same juice canned 3 weeks previously.

Both the groups given fresh juice made much greater weight gains than the group given 1 mg. ascorbic acid daily; the group given canned juice gained slightly less. The canned juice contained about 1000 mg. vitamin C per 100 ml. according

to the biological comparison, and 1100 mg. per 100 ml. by chemical analysis. Similar results were obtained in a curative experiment.

EWERBECK, H. and LEGERSKI, R. Experimenteller Beitrag zur Frage: Verhütet Vitamin P den Transfusionszwischenfall? [Experimental contribution to the question whether vitamin P has a protective action against transfusion accidents.] *Monatsschr. Kinderheilk.*, 1955, 103, 21-23. [Kinderklin., Univ. Cologne.]

In 33 tests on 20 rabbits sensitised to human red cells or whole blood, no evidence was obtained that vitamin P as rutin could protect against anaphylactic shock. No effect was observed whether rutin was administered before, at the same time as, or after, the shock dose of blood or red cells. In view of the findings it was considered unlikely that vitamin P would protect against anaphylactic shock occurring during blood transfusion.

HURLBERT, R. B. and REICHARD, P. The conversion of orotic acid to uridine nucleotides *in vitro*. *Acta chem. scand.*, 1955, 9, 251-262. [Dept. Biochem., Karolinska Inst., Stockholm.]

Particle-free extracts of rat, pigeon and chick tissues were tested for their ability to convert orotic acid containing ^{14}C into the nucleotides of 5'-uridine monophosphate and 5'-uridine pyrophosphate. Ribose-5-phosphate, adenosine triphosphate and Mg were required for the conversion. Extracts of liver, pancreas and spleen were the most active in the process; extracts of tumour and kidney were less so, and heart muscle had almost no effect. It was shown that ribose-5-phosphate and adenosine triphosphate reacted to produce ribose triphosphate which was the source of the ribose phosphate moiety of the uridine nucleotides. The nucleotide of 5'-uridine monophosphate appeared to be formed first; other nucleotides were produced later by phosphorylating enzyme systems present in the tissue extracts.—A. M. Copping.

LEUBNER, H. and SHWACHMAN, H. **Studies of duodenal fluid in nutritional disorders. Alkaline phosphatase.** *Amer. J. Dis. Child.*, 1955, 89, 341-345. [Child. Med. Centre, Div. Labs. Res., Harvard Med. Sch., Boston, Mass.]

Fasting values of alkaline phosphatase in duodenal fluid are tabulated for 9 adults, 17 healthy children and 94 children suffering from nutritional and other disorders. Estimations of digestive enzymes, bile concentration and acid phosphatase in duodenal fluid showed no relation between either alkaline or acid phosphatase and the digestive enzymes or bile concentration. It is suggested that much of the alkaline phosphatase in duodenal fluid arises from the duodenal mucosa itself.

The lack of association between alkaline phosphatase and bile in duodenal fluid from fasting subjects was found also in subjects given intra-duodenal instillations of olive oil.—F. C. Aitken.

BLOCK, W. D. and JOHNSON, D. V. **Factors influencing xanthine oxidase activity in rat skin.** *Arch. Biochem. Biophys.*, 1955, 56, 137-142. [Dept. Dermatol., Med. Sch., Univ. Michigan, Ann Arbor.]

Details are given of a method for preparing skin extracts from rats which were weaned at 21 days and maintained on a standard Rockland rat diet.

Vol. 25, No. 4

The method gave reasonably consistent values for skin xanthine oxidase when tested on a large number of adult rats. Skin and liver xanthine oxidase were estimated at 7, 14, 21, 28, 36, 45 and 90 days of age.

Xanthine oxidase in skin did not change significantly during the first 21 days after birth; an increase occurred from 21 to 28 days of age, corresponding to the first 7 days on the stock diet. The effect of the change in diet on liver xanthine oxidase was less; there was a gradual increase in activity with age. A 72-hr. fast did not affect the level of xanthine oxidase in skin extracts; liver xanthine oxidase was depleted.—G. F. Garton.

BÉRAUD, T. and VANNOTTI, A. **Variations du taux du cytochrome C dans les états d'inanition chez le lapin. [Variations in the concentration of cytochrome c in inanition in the rabbit.]** *Schweiz. med. Wochenschr.*, 1955, 85, 174-178. [Clin. Méd., Univ. Lausanne.]

Cytochrome c was estimated by a photometric method in the liver of fed and fasting rabbits. The presence of large amounts of glycogen or fat in the liver did not appear to affect the extraction of cytochrome c, which showed a difference in distribution in the cell elements between fed and fasting animals. There was a large increase in cytochrome c of the liver after a 48-hr. fast. The effect of fasting was still apparent in rabbits poisoned with lead or allyl-isopropylacetylcarbamide, though the amount of cytochrome c was diminished. The relation of cytochrome c to the formation of haem in normal and abnormal conditions is discussed.

DIGESTION AND ABSORPTION

5040

NESSENT, R., LECHT, M. and SCHEVEN, B. Über die Durchgangszeit des Futters beim Silberfuchs. [The rate of passage of feed in the silver fox.] *Arch. Tierernährung*, 1955, 5, 26-32. [Inst. Tierzuchtforsch., Rostock, Dummerstorf.]

Foxes fed twice daily were given a meal marked with carbon black and faeces were collected until the marker disappeared. Whether the meal so marked was given in the morning or the evening, the marker appeared in the faeces after about 8 hr. in adult foxes and after about 6½ hr. in 4 foxes 4 months old. The marker was eliminated by 18 or 19 hr. in both young and adult foxes when it was given in the morning and by 29 to 30 hr. when it was given in the evening. The digestion time of the evening feed was thus nearly twice that of the morning feed.

In foxes fed only once daily the first marked faeces appeared in 5 to 10 hr. and the last in 31 to 32 hr., irrespective of age and sex.

The emptying time of the stomach was studied in 36 foxes given a meal marked with stained straw particles 2 to 26 hr. before they were killed. Not more than 10 per cent. of the meal usually left the stomach in the first 8 or 10 hr., but 10 per cent. remained after 26 hr., by which time 68 per cent. was in the large intestine.

It is concluded that fluid may pass through the digestive tract of foxes at 90 cm. an hour, and the whole meal at 12, 7 or 6.5 cm. an hour when feeding is twice daily in the morning or afternoon or once daily.—D. Duncan.

5041

THACKER, E. J. and BRANDT, C. S. Coprophagy in the rabbit. *J. Nutrition*, 1955, 55, 375-385. [U.S. Plant, Soil and Nutrit. Lab., Bur. Plant Indust., U.S. Dept. Agric., Ithaca, N.Y.]

Pairs of rabbits, male and female, were given at 4 weeks of age diets consisting mainly of dried grass (roughage diet) or of purified components (purified diet). At 14 weeks the animals were given a maintenance level of feed and one from each pair was tied up to prevent coprophagy. After 10 days radio-active Cr_2O_3 was given mixed with one day's feed. Faeces were collected for 10 days from the tied rabbits and for 30 days from the others. After this time the situation was reversed and the procedure was repeated. Urine and faeces for the fourth to tenth days were pooled for digestibility and N balance estimations. Throughout 2 years 3 groups, each of 4 rabbits, were studied.

The prevention of coprophagy produced an apparent decrease in protein digestibility and in N retention and in the digestibility of dry matter on both diets. The effect of coprophagy on the utilisation of other dietary nutrients depended on the diet. In rabbits practising coprophagy there was greater digestibility of the cellulose of the purified diet and a longer half-life of feed residues in the digestive tract.

A physiological mechanism to explain the production of soft and hard faeces is suggested; differences in composition are accounted for by the production of a protein-containing caecal secretion.

G. F. Garton.

5042

MÜTING, D. Über den Aminosäuregehalt des menschlichen Magen- und Duodenalsaftes. [The amino-acid content of human gastric and duodenal secretion.] *Naturwissenschaften*, 1954, 41, 580. [Forschungs Inst. Diabetes Karlsburg, Kr. Greifswald.]

By methods described elsewhere (Abst. 626, Vol. 25), 18 amino-acids were estimated by chemical methods or paper chromatography in 35 samples of gastric secretion, fasting and after stimulation with caffeine, and 15 samples of duodenal secretion from 10 normal persons and 40 controlled diabetics without stomach trouble. The results are tabulated. The total amounted to rather less than 6.25 times the α -amino-N estimated by the method of Moore and Stein (Abst. 3939, Vol. 18), since the latter includes peptides that react with ninhydrin. Gastric secretion after caffeine contained more α -amino-N than fasting secretion, and highly acid secretion more than normal or anacid secretion.

5043

PERSIDSKII, V. YA. Vliyanie kakao na sekretornuyu i evakuatornuyu funktsii zheludka. [Influence of cocoa on secretion and emptying of the stomach.] *Vop. Pitan.*, 1955, 14, No. 2, 30-34. [Inst. Med., Kiev.]

The response of the stomach to cocoa was tested by fractional aspiration in 18 subjects whose gastric function varied from hypersecretion, through the normal range, to complete achylia. Cocoa stimulated gastric secretion, mainly in the second phase. Cocoa left the stomach more slowly than water, ethanol or meat broth. Cocoa prepared with milk left the stomach more slowly and led to a lower concentration of free acid than did cocoa prepared with water.—D. W. Taylor.

5044

BRACKNEY, E. L., THAL, A. P. and WANGENSTEIN, O. H. Role of duodenum in the control of

N.A. and R., October 1955

gastric secretion. *Proc. Soc. Exp. Biol. Med.*, 1955, **88**, 302-306. [Dept. Surg., Univ. Minnesota, Minneapolis.]

After the preparation and standardisation of Heidenhain gastric pouches, 5 dogs were subjected to removal of the duodenum and the first 20 to 30 cm. of jejunum, the common bile duct and pancreatic duct being anastomosed to the jejunum. In 3 more dogs the same length of duodenum and jejunum was transplanted to a site about half way down the remaining small intestine. The dogs had good appetites and maintained their weights. Study of gastric secretion from the pouches commenced 3 weeks after the second operation.

All dogs showed a large increase in the amount of free HCl secreted during 8-hr. collections after removal or transplantation of the duodenum. The increase was from 84 to 820 per cent. of the pre-operative secretion and was always statistically significant.—D. Duncan.

5045

HERTING, D. C. and AMES, S. R. On the gastric lipolysis of fat. *Arch. Biochem. Biophys.*, 1955, **55**, 295-297. [Res. Labs., Distillation Products Industries, Div. Eastman Kodak Co., Rochester, N.Y.]

Adult rats were fed for 5 or 6 days on diets which contained 22.1 per cent. of cottonseed oil, I value 110, steam-rendered lard, I value 55, or fully hydrogenated lard, I value 0. Lipids were then extracted from the stomach contents and free fatty acids were titrated.

Values of 7.7 and 8.8 per cent. free fatty acids were found in the lipids after cottonseed oil and lard, respectively, and 49.9 per cent. after saturated fat. It is suggested that this may be explained by delayed emptying of the stomach or by slow dissociation of lipase-substrate complex.

HÉDON, L. and MACABIES, J. Étude quantitative de l'absorption intestinale des protides chez les chiens ayant subi différentes sortes d'altérations pancréatiques. [Quantitative study of absorption of protein from the intestine in dogs subjected to interference with the pancreas.] *C.R. Soc. Biol.*, 1955, **149**, 159-161.

The 6 dogs were fed on lean horsemeat and bread. In one the pancreas had been removed a month before the experiment and insulin was given; 3 had part of the pancreas removed and required no insulin, although one had glycosuria; 2 had diabetes produced by alloxan and were maintained with insulin. The absorption of protein was estimated from the calculated composition of the diet and from the total N content of the faeces.

The alloxan-diabetic dogs absorbed protein normally. The dog with all the pancreas removed and the 2 with part removed and no diabetes excreted from 20 to 35 per cent. of their protein intake in the faeces, but in the other, which was left with about 2 g. of pancreatic tissue round the canal of Wirsung, and thus secreted into the intestine some pancreatic juice, the loss of protein was only 8.6 per cent. Pancreatic juice given to one dog and raw beef pancreas to another did not improve protein digestion, but further experiments of this sort are proposed.—D. Duncan.

5051

HARRIS, R. S., CHAMBERLAIN, J. W. and BENEDICT, J. H. Digestion of neutral fats by human subjects. *J. Clin. Invest.*, 1955, **34**, 685-689. [Dept. Food Technol., Massachusetts Inst. Technol., Cambridge.]

Free fatty acids, total monoglycerides, and 1-monoglycerides were estimated in the lipids recovered by intubation from the intestinal lumen of 7 healthy young men at intervals up to 2 hr. after each had drunk 45 ml. of a 3:1 mixture of

soya bean oil and cottonseed oil hydrogenated to I value 80.

Monoglycerides totalled up to 13 per cent. of the total lipids; 50 to 66 per cent. of the monoglycerides was 2-monoglyceride. The free fatty acid content of the lipids was 2 to 3 times the total monoglyceride content.

In further experiments, each of 3 subjects was given a meal containing 45 g. of the same triglyceride mixture; no significant difference in the proportions of products of fat digestion was found.

COURMOULIS, M., GISINGER, E. and NEUMAYR, A. Eisenmangel und Fettresorption. Zur Störung der Fettresorption nach Magenresektionen. [Iron deficiency and fat absorption. Disturbance of fat absorption after resection of the stomach.] *Deutsch. med. Wochenschr.*, 1955, 80, 810-812. [2. Med. Klin., Univ. Vienna.]

Estimations of fat absorption, serum Fe and total Fe-binding capacity, Hb and red cell count were made on 26 patients who had had their stomachs removed by the Billroth II operation and had little or no sign of jejunitis; the results are tabulated and shown graphically. The patients were classified in 3 groups. Five had almost normal fat absorption, no anaemia, no Fe deficiency. Ten, of whom 8 were women, had much reduced fat absorption; all but one had anaemia and Fe deficiency; in the exception the condition was masked, but was revealed by the improved values after treatment with Fe. Eleven with moderately reduced fat absorption had anaemia but no Fe deficiency. Possible ways in which Fe deficiency can affect fat absorption are discussed.

5055

SWELL, L., FLICK, D. F., FIELD, H. (Jr.) and TREADWELL, C. R. Role of fat and fatty acid in absorption of dietary cholesterol. *Amer. J. Physiol.*, 1955, 180, 124-128. [Gen. Med. Res. Lab., Veterans Admin. Centre, Martinsburg, W. Va.]

Groups of rats were fed for 21 days on cholesterol-free diets containing 25 per cent. soya bean oil which had been partly hydrogenated to yield products of I value 14.2, 34.2, 60.9 and 81.0. Total and ester cholesterol were estimated weekly in whole blood. Blood cholesterol varied with the I value of the dietary fat; animals given the most unsaturated oil had 16 per cent. more blood cholesterol than control animals; the increase was greatest in the ester fraction.

In further experiments the diets contained 2 per cent. cholesterol, 1 per cent. Na taurocholate and 25 per cent. linoleic acid, oleic acid, stearic acid, peanut oil, maize oil or linseed oil. The blood cholesterol rose in all animals, particularly in those given free fatty acids. *In vitro*, cholesterol was more rapidly esterified with free fatty acids, especially unsaturated acids, than with fatty acids derived from intact triglycerides, with a homogenate of fresh pig pancreas as the enzyme system.

In other experiments groups of rats were given diets containing cholesterol 2, Na taurocholate 1, and olive oil 25 per cent., separately or in combinations. Blood cholesterol was estimated weekly for 3 weeks. The results showed that fat need not be present in the diet for the absorption of dietary cholesterol, provided that enough bile salt is present.—G. A. Garton.

5056

SWELL, L., BOITTER, T. A., FIELD, H. (Jr.) and TREADWELL, C. R. Absorption of dietary cholesterol esters. *Amer. J. Physiol.*, 1955, 180, 129-132. [Gen. Med. Res. Lab., Veterans Admin. Centre, Martinsburg, W. Va.]

Groups of rats were fed for 21 days on diets containing 25 per cent. olive oil and 2 per cent. of either cholesterol, cholesterol butyrate, cholesterol oleate or cholesterol linoleate, both with and without 1 per cent. Na taurocholate. Blood cholesterol was estimated weekly.

Rats given cholesterol or cholesterol butyrate showed greater increases in blood total and ester cholesterol than those given cholesterol oleate or linoleate; the increases were greater when Na taurocholate was included in the diet.

Cholesterol butyrate was hydrolysed more rapidly *in vitro* by pig pancreas homogenate than was oleate or linoleate.

It is suggested that cholesterol must be in the free form before it can be absorbed.—G. A. Garton.

- NICHOLS, R. E., MOORE, W. E. C. and DILLON, R. D. The effective buoyancy of the rumen juice of cattle fed hay, grass and fresh legumes. *J. Animal Sci.*, 1955, 14, 276-278. [Wisconsin Agric. Exp. Stat., Madison.]

The effective buoyancy of rumen juice may be measured by its specific gravity. This will be changed by the type of feed, since heavier feeds sink before rumen digestion is completed, and the subsequent gaseous action will give rise to a frothy rumen fluid with low sp. gr. This was demonstrated in a test with 2 cows with rumen fistulae. The sp. gr. of the ventral sac fluid was measured before, $\frac{1}{2}$ hr. after and 2 hr. after they had been given feeds of hay, fresh grass, fresh alfalfa or fresh clover. The last 2 were considered to be the heavier types of feed, and the results showed that they reduced effective buoyancy, as indicated by sp. gr. of the rumen juices.—T. D. Bell.

- TURNER, A. W. and HODGETTS, V. E. Buffer systems in the rumen of the sheep. 1. pH and bicarbonate concentration in relationship to p_{CO_2} . 2. Buffering properties in relationship to composition. *Austral. J. Agric. Res.*, 1955, 6, 115-124; 125-144. [Div. Animal Health Prod., C.S.I.R.O., Animal Health Res. Lab., Parkville, Victoria.]

1. Rumen fluid collected through a fistula and cooled under liquid paraffin to room temperature maintained its pH of 6.60 for about 3 hr. In air the pH rose and stabilised after about 150 min. at 8.90; it behaved similarly when gassed with

hydrogen, but the change was partly reversed when rumen gases were bubbled through.

Ruminal gas obtained by puncture contained 58.5 per cent. CO_2 . Contents in contact with the gas had a pH of 6.63, but when the rumen fistula had been open for 9 min. the percentage of CO_2 in the gas had fallen to 3.2, and the pH of fluid at the surface had risen to 6.82. In sheep on different diets the ruminal gas contained from 28.3 to 72.8 per cent., mean about 50, a p_{CO_2} about 5 to 13 times that of arterial blood. The pH of fluid collected by stomach tube was higher than that of fluid collected through a fistula. The effects of p_{CO_2} on the pH and bicarbonate ion content of rumen fluid according to the Henderson Hasselbalch equation are tabulated.

For routine estimation of pH in rumen contents a mixture of equal part of CO_2 and nitrogen is recommended.—D. Duncan.

2. A detailed examination of the buffering systems in rumen liquor is described. Titration curves show that the liquor is well buffered on the acid side of neutrality and poorly buffered on the alkaline side. The important components are bicarbonate and phosphate. The time spent in feeding, the nature of the feed and the consumption of drinking water all affect buffering capacity.

In the fasting animal bicarbonate is the most important component; after feeding, as the pH falls and loss of CO_2 occurs, phosphate becomes more important, and the volatile fatty acids contribute significantly only when the pH falls below 6.

A. T. Phillipson.

COMPOSITION OF BODY FLUIDS AND TISSUES

BLOOD

5066

PASSARO, G. and SICILIANO, G. Il volume del liquido extracellulare nel neonato. [Volume of the extracellular fluid in the newborn.] *Bol. Soc. ital. Biol. sper.*, 1953, 29, 1322-1325. [Ist. Clin. Pediatr., Univ. Rome.]

The volume of extracellular fluid was estimated by the thiocyanate method within 3 hr. of birth in 30 infants weighing from 2200 to 4370, mean 3456 g. The mean volume of extracellular fluid was 1055 ml. with range 827 to 1447, representing a mean percentage of bodyweight of 30.7 with range 24.5 to 39.8. The proportion did not differ significantly for different bodyweights unless the infant was premature, when the percentage was higher. The percentage was 50 per cent. higher than that accepted as normal for adults.—E. M. Hume.

5067

IKKOS, D., LJUNGGREN, H., LUFT, R. and SJÖGREN, B. Content and distribution of potassium and chloride in adults. *Metabolism*, 1955, 4, 231-237. [Div. Endocrinol., Dept. Int. Med., Serafimerlasarettet, Stockholm.]

Exchangeable K and Cl were estimated in 21 adult subjects by the dilution of the radio-active isotopes ^{42}K and ^{82}Br . Extracellular Cl was calculated as the product of plasma water chloride concentration and extracellular water volume estimated with inulin or thiosulphate. Intracellular Cl was taken as the difference between total and extracellular values. Intracellular K was computed by subtracting 50 m. equiv. from the exchangeable K.

Exchangeable K was on the average, in m. equiv., 45 per kg. bodyweight, 1661 per sq. m. surface area and 81.2 or 87.9 per litre of total body water measured with D_2O or antipyrine. Corresponding values for exchangeable Cl were 29.5, 1087, 53.4 or 56.1. Extracellular Cl contained 58.2 or 56.6 per cent. of the total, depending on whether inulin or thiosulphate was used for estimation. The mean intracellular Cl was 31.3, 32.0, 34.0 and 33.7 m. equiv. per litre when measured with D_2O and inulin, D_2O and thiosulphate, antipyrine with inulin and antipyrine with thiosulphate, respectively. Corresponding values for K were 111, 110, 121 and 122. The accuracy of the calculations is discussed.—A. Hepburn.

GARROW, J. S. Some haematological and serum protein values in normal Jamaicans. *West Indian Med. J.*, 1954, 3, 104-107. [Univ. Coll. West Indies, Jamaica.]

The serum protein values found in apparently normal and well nourished male and female Jamaicans did not correspond with those of similar Europeans. The most marked differences were in the mean corpuscular Hb concentration and in the mean values for serum albumin and globulin. In the Jamaicans the range of the mean corpuscular Hb concentration was from 26 to 36 per cent., compared with from 32 to 36 per cent. in Europeans and the values in g. per 100 ml. for serum albumin and globulin, respectively, ranged for Jamaicans from 2.4 to 5.5 and from 2.0 to 5.5, and for Europeans from 4.3 to 5.0 and from 1.1 to 3.1. The erythrocyte sedimentation rate had a greater range in Jamaicans than in Europeans.—L. Wills.

TURNBULL, E. P. N. and WALKER, J. Haemoglobin and red cells in the human foetus. 2. The red cells.

WALKER, J. and TURNBULL, E. P. N. 3. Foetal and adult haemoglobin. *Arch. Dis. Childhood*, 1955, 30, 102-110; 111-116. [Dept. Midwifery, Univ. Aberdeen.]

For earlier work [not numbered as Part 1] see Title 590, Vol. 24.

2. Packed cell volume, mean cell diameter and reticulocyte count were measured and absolute values were calculated for red blood cells in the cord blood of human foetuses from the 10th to the 43rd week of clinically normal pregnancy. The changes occurring as pregnancy advanced were, in the Price Jones curve, movement to the left with narrowing of base and increase in height and, in the numbers of cells under $9\ \mu$. in diameter, a steady increase, those $9\ \mu$. or more remaining nearly constant in number. Deficiency of oxygen

N.A. and R., October 1955

supply in the later weeks altered the picture and variations in that supply are considered responsible for the wide distribution of packed cell volumes and mean volumes and perhaps for variations in the numbers and proportions of cells of different sizes found in individual foetuses.

3. The percentages of foetal and adult Hb were estimated in the blood of human foetuses. No difference in the proportion of the adult form, first detected at the 13th week, was found between the normal and abnormal pregnancies studied. The increase in total Hb in later weeks of pregnancy, which was stimulated by anoxia, was found to be almost wholly in the foetal form. The findings are discussed in relation to those in the previous paper and to the view that the two forms of Hb are contained in separate foetal and adult types of corpuscle.—D. Harvey.

HUISMAN, T. H. J., JONKIS, J. H. P. and VAN DER SCHAAF, P. C. **Amino-acid composition of four different kinds of human haemoglobin.**

PRINS, H. K. and HUISMAN, T. H. J. **Chromatographic estimation of different kinds of human haemoglobin.** *Nature*, 1955, 175, 902-903; 903-904. [Dept. Paediat., Univ. Groningen.]

Electrophoretically pure samples of different haemoglobin, from blood from normal adults, the umbilical cord, patients with sickle cell anaemia (Hb B) and patients with the homozygous character Hb C were analysed. Foetal Hb contained almost 6 times as much isoleucine as adult Hb, more threonine, serine and methionine, and less proline, valine, tyrosine and histidine. Hb B was not different from the normal and Hb C differed only in having more lysine and histidine.

The 4 types were quantitatively separated by ion-exchange chromatography.—A. Hepburn.

5073

VAN DER SCHAAF, P. C. and HUISMAN, T. H. J. **The amino-acid composition of human adult and foetal carbonmonoxyhaemoglobin estimated by ion exchange chromatography.** *Biochim. biophys. Acta*, 1955, 17, 81-91. [Dept. Paediat., Univ. Groningen.] French and German summaries.

Hb from normal adults and purified foetal Hb were saturated with CO and analysed by ion-exchange chromatography for 17 amino-acids. Foetal carboxyhaemoglobin contained more threonine, serine, methionine and isoleucine and less proline, alanine, valine and tyrosine than adult. The greatest differences were in serine, isoleucine and valine. Serine, threonine, aspartic acid, methionine, tyrosine and lysine decreased linearly with the time of hydrolysis from 24 to 144 hr. and the original amounts were obtained by extra-

polaration. The yields of the other amino-acids remained constant and it was therefore considered unlikely that isoleucine and valine were combined in peptide linkage. As the numbers of amino-acid residues calculated for a molecular weight of 68,000 were not all divisible by 4, adult and foetal globins were considered not to consist of 4 identical polypeptide chains.—A. Hepburn.

RUSOFF, L. L., SCHEIN, M. W. and VIZINAT, J. J. **Blood studies of red Sindh-Jersey crosses: 3. Effect of a fixed hot environment on blood constituent levels of Jerseys and Sindh-Jersey crosses.** *Science*, 1955, 121, 437-438. [Louisiana Agric. Exp. Stat., Baton Rouge.]

For part 1 see Abstr. 669, Vol. 22.

Jersey and Sindh \times Jersey cows with $\frac{3}{4}$, $\frac{1}{2}$, or $\frac{1}{4}$ Sindh blood were used to compare Hb, haematocrit, plasma Ca and plasma inorganic P values. These values were estimated 3 times during a year, 18 hr. before, immediately after and 18 hr. after 6 hr. of exposure to a high temperature, 92° F. wet bulb, 105° F. dry bulb.

There was no significant difference with breed or season between the values, which therefore could not serve as indicators of heat tolerance.

T. D. Bell.

MORRIS, B. and COURTICE, F. C. **The protein and lipid composition of the plasma of different animal species determined by zone electrophoresis and chemical analysis.** *Quart. J. Exp. Physiol.*, 1955, 40, 127-137. [Kane-matsu Mem. Inst. Pathol., Sydney Hosp.]

Plasma from man, dog, cat, rat, mouse, rabbit, guinea-pig, sheep, horse, ox and goat was examined. There were specific differences in absolute amounts of protein and lipids and their relative distribution. In man most lipids were associated with the β -globulins; in the dog and cat almost all the lipids were bound by the α -globulins. The herbivora in general had low levels of lipids and lipoprotein, but relatively much α -lipoprotein; the horse had higher levels of lipids and lipoproteins than the ruminants.—A. Hepburn.

DUNLAP, J. S. and DICKSON, W. M. The effect of age and pregnancy on ovine blood protein fractions. *Amer. J. Vet. Res.*, 1955, 16, 91-95. [Dept. Vet. Pathol., State Coll. Washington, Pullman.]

Serum total protein, albumin and globulin were estimated weekly during gestation in 5 pregnant ewes over a year old. Serum globulin values fell during the second half of pregnancy. Serum albumin fell slightly during the first half, but returned to initial values at parturition. Total protein fell throughout, probably reflecting the changes in fractions.

In 6 lambs, from these ewes and one other, serum protein, albumin and globulin were estimated weekly from 7 to 17 weeks of age. Globulin increased steadily, but there was no change in albumin.

Ewes had significantly higher serum globulin values than lambs, but there was no difference in albumin.—T. D. Bell.

5086

DINGLEDEINE, W. S., PITT-RIVERS, S. and STANBURY, J. B. Nature and transport of the iodinated substances of the blood of normal subjects and of patients with thyroid disease. *J. Clin. Endocrinol.*, 1955, 15, 724-731. [Dept. Med., Harvard Med. Sch., Boston, Mass.]

The binding powers of serum proteins for thyroxine, triiodothyronine and iodide were compared in an attempt to detect abnormal constituents in the sera of hyperthyroid patients. The serum came from 27 patients, 17 of whom had thyrotoxicosis, and sometimes serial samples were obtained over the first 6 days after administration of ^{131}I . Some of the doses of ^{131}I were therapeutic, others were only tracer doses.

Thyroxine was transported in the plasma mainly by the protein which has electrophoretic mobility between α_1 - and α_2 -globulin. In addition, a small fraction of serum thyroxine was bound to albumin. The sera of thyrotoxic and normal subjects did not differ in this respect. Triiodothyronine was found *in vitro* in all the proteins, but this may have been due to overloading *in vitro*, as the absolute amount of triiodothyronine relative to thyroxine *in vivo* is unknown. There was no evidence of an abnormal iodine-containing component in the sera of the hyperthyroid patients, but the possibility remains that a non-iodinated constituent may exist in the serum of patients with Graves' disease.

The electrophoretic and chromatographic methods are given in detail.—B. W. Simpson.

CHARKEY, L. W., KANO, A. K. and HUGHAM, D. F. Effects of fasting on blood non-protein amino acids in humans. *J. Nutrition*, 1955, **55**, 469–480. [Dept. Chem., Colorado Agric. and Mech. Coll., Fort Collins.]

Leucine and valine in the blood of 6 adults increased after they had fasted for 48 hr. Lysine, threonine, methionine, arginine and tryptophan decreased. These amino-acids responded differently to a fast in chickens (Absts. 485, Vol. 24; 2014, Vol. 25). D-Leucine is not utilised by man, the D-isomers of lysine, threonine, methionine, arginine and possibly tryptophan are utilised, but no information is available for D-valine. It is suggested that those amino-acids not metabolically derivable from their D-isomers are increased in the blood during fasting.—A. Hepburn.

5089

BALDRIDGE, R. G. Blood ergothioneine and dietary oats. *J. Nutrition*, 1955, **56**, 107–113. [Dept. Biol. Chem., Med. Sch., Univ. Michigan, Ann Arbor.]

Male rabbits and rats were given several diets and blood ergothioneine was estimated after several weeks. Ergothioneine appeared in the red blood cells of all animals after they had been fed on oats. In the rat the blood level was related to the percentage of oats in the diet; none was found in rats given purified diets or such diets supplemented with cabbage. The administration of vitamin B₁₂ had no effect on blood ergothioneine in the rat. Elevated levels of blood ergothioneine were not related to thyroid function, as far as was shown by histological examination and relative weight of thyroid tissue.—G. F. Garton.

5090

RAFSTEDT, S. Studies on serum lipids and lipoproteins in infancy and childhood. *Acta paediat.*, 1955, **44**, Suppl. 102, pp. 109. [Paediat. Clin., Univ. Lund.]

Methods are described whereby total lipids, total and free cholesterol, lipid P and lipoproteins could all be estimated in a total of 0.6 ml. serum,

so that serial analyses could be made even in newborn premature infants.

Serum lipids and lipoproteins were estimated in the first 10 days of life in 30 full-term infants delivered normally from healthy mothers and 2 delivered by caesarean section. In cord blood all the values were lower than those of normal adults. α -Lipoproteins represented 43 and β -lipoproteins 33 per cent. of the total, against about 30 and 50 per cent. in adults. In the first 12 hr. of life total lipids, cholesterol and phospholipids increased by 10 or 15 per cent., possibly because of dehydration. In the first few days all the serum lipids increased steadily, but by the fourth day α -lipoproteins had fallen to 20 and β -lipoproteins had risen to 46 per cent. of the total. The ratio of combined to free cholesterol was from 1.3 to 2.3:1 in cord blood, and remained unchanged for the first few days despite absolute increases in both combined and free cholesterol.

The second group consisted of 37 infants in the first year of life, admitted to the hospital or infants' home on social grounds. In individual infants there was wide variation in values for serum lipids and lipoproteins, but the spread was less than that of the whole group. Values tended to rise towards the end of the first year and so did the ratio of combined to free cholesterol. The ratio of cholesterol to phospholipids was lower than in adults.

The third group contained 25 children 2 to 14 years old, healthy or referred to hospital for examination or for mental disorders. All the results differed very significantly from those in the infants, falling in the range of adult values.

The premature group consisted of 19 infants who weighed at birth from 1350 to 2340 g. Prematurity was not due to any known disease. Lipid values in cord blood were similar to those for full term infants, but phospholipids were lower. The increases in total lipids and cholesterol in the first days were less than in full-term infants, but there was no other difference. After the first month there was no difference between full-term and premature infants.

In 7 pairs of twins, mostly premature, all the values in cord blood were closely similar between the twins, but they did not always follow the same course later.

Three small groups consisted of infants not given breast milk, mostly infants from unmarried mothers and destined for immediate adoption. For the first 3 or 4 days they received either low-fat milk with citric acid, or sugar and a casein hydrolysate, or maltose solution alone. On the first 2 of these diets increases occurred in serum lipids and lipoproteins, but the increases were less than those on normal diet; with maltose alone there was no increase in serum lipids, and in some

infants even a decrease, and the relative percentage of the lipoprotein fractions remained steady. Normal values were quickly reached when the infants were given ordinary diet.—D. Duncan.

5091

DANGERFIELD, W. G. and SMITH, E. B. **An investigation of serum lipids and lipoproteins by paper electrophoresis.** *J. Clin. Pathol.*, 1955, 8, 132-139. [Dept. Pathol., St. Bartholomew's Hosp., London.]

The lipid and lipoproteins in about 400 samples of human serum were examined. Methods are described for preparing and staining electrophoretic strips for protein, fat and cholesterol; the distribution of these components in normal and pathological sera is illustrated in photographs and discussed in relation to electrophoretic studies by other investigators.—G. A. Garton.

5092

HELLYARD, L. A., ENTENMAN, C., FEINBERG, H. and CHAIKOFF, I. L. **Lipide and protein composition of four fractions accounting for total serum lipoproteins.** *J. Biol. Chem.*, 1955, 214, 79-90. [Dept. Physiol., Sch. Med., Univ. California, Berkeley.]

Serum of man, dog, rabbit, rat and chicken was separated by ultracentrifugal flotation into 4 fractions which accounted for all the lipoprotein present; each fraction was analysed for protein, free and esterified cholesterol, phospholipins and triglycerides. The amount of each lipoprotein fraction differed considerably among the 5 species studied; in the dog, rat, rabbit and chicken the range of intraspecific variation was small, but the human sera showed considerable variation. There was much more total lipoprotein in man, chicken and dog than in the rat and rabbit. The identity of the lipoprotein fractions is discussed.

G. A. Garton.

5093

BILLING, B. H., HASLAM, R. M., HEIN, D. E., CONLON, H. J., HAMILTON, D. L., MYNDRUM, G. M. and SCHIFF, L. (with DOHM, L. and STARR, C.) **Serum and liver lipids in patients with and without liver disease.** *J. Lab. Clin. Med.*, 1955, 45, 363-370. [Dept. Int. Med., Coll. Med., Univ. Cincinnati, Ohio.]

The material consisted of 85 liver samples obtained by needle biopsy and classified on histological diagnosis. There were 20 without liver abnormality, 11 with cirrhosis of nutritional type, 13 with other types of cirrhosis or fibrosis, 12 with viral hepatitis and smaller numbers with other liver disorders. Estimations of serum lipids were made usually within 2 days of liver biopsy.

Individual results are tabulated. The only group in which there was significant association between

total lipid values of serum and liver was the group with cirrhosis, but even here the serum lipid could not be used to predict the liver lipid.—D. Duncan.

COURTICE, F. C. and MORRIS, B. **The exchange of lipids between plasma and lymph of animals.** *Quart. J. Exp. Physiol.*, 1955, 40, 138-148. [Kanematsu Mem. Inst. Pathol., Sydney Hosp.]

Zone electrophoresis and chemical analysis were used in a study of the protein and lipid composition of lymph collected from different ducts of the dog, cat, rabbit and rat. All the components present in the plasmas were identified in the lymph, but in lower concentrations. The plasma to lymph gradients for lipids and proteins were similar and were greater in cervical duct lymph than in thoracic duct lymph. With the high-speed centrifuge (20,000 g), large amounts of fat which appeared in thoracic duct lymph were removed without any significant change in the post-absorptive lymph protein and lipoprotein electrophoretic patterns.

The disappearance of particulate fat from the circulation is discussed, and it is suggested that during alimentary lipaemia some chylomicrons may escape through capillary membranes without degradation to smaller lipoprotein complexes.

5097

SWANSON, P., LEVERTON, R., GRAM, M. R., ROBERTS, H. and PESEK, I. **Blood values of women: cholesterol.** *J. Gerontol.*, 1955, 10, 41-47. [Home Econ. Res., Iowa Agric. Exp. Stat., Ames.]

Cholesterol in serum from 184 healthy women aged from 18 to 92 years had a mean value of 209 ± 48.2 mg. per 100 ml. The mean rose from 163 in the third to 260 mg. in the seventh decade (mean ages 20.0 and 63.4 years) and then declined. The cholesterol concentration was not significantly related to bodyweight, basal metabolic rate, diastolic blood pressure or fat or protein intake.

TJONG, B. K. Onderzoekingen over de invloed van de voeding en van enkele andere factoren op het cholesterolgehalte van het bloedserum, in verband met het vraagstuk der atherosclerose. [Studies of the effect of diet and certain other factors on the cholesterol content of blood serum, with reference to the problem of atherosclerosis.] *Thesis, Amsterdam*, 1954, pp. 78. English summary.

Sixty healthy volunteers took, in varying succession, an almost exclusively vegetable diet, a plain ordinary diet and a rich diet of about the same energy value. Weight, B.M.R., electrocardiograms and clinical data were recorded as well as blood cholesterol. The results are presented as individual and composite charts. Individuals differed greatly in their reactions to the diets. In general blood cholesterol rose or sank with the cholesterol intake, but some subjects maintained a high level even on the vegetarian diet and some a low level on the rich diet. Basal metabolism and electrocardiogram showed no change. Body-weights varied by small but significant amounts with cholesterol intake. Infections and emotional upset or extra exercise tended to reduce blood cholesterol irrespective of diet; sometimes the changes during infection were considerable and were followed by increases during convalescence to levels above that to be expected from the diet in question. There was no sex difference in the reactions.—I. Leitch.

POMERANZE, J. and CHESSIN, M. Decholesterolizing agents. *Amer. Heart J.*, 1955, 49, 262-266. [New York Med. Coll. Flower and Fifth Ave. Hosps.]

The effects of several substances on serum cholesterol were studied. In 18 untreated subjects serum cholesterol was estimated every 7 to 10 days for from 2 to 13 weeks and considerable fluctuation was found, especially in subjects with high levels. No effect on serum cholesterol was observed in 25 subjects given 7 g. sitosterol daily for 6 weeks, or

13 given Chophytol, a Jerusalem artichoke preparation, for 3 weeks, 12 given polysorbate-80-choline-inositol complex for 6 weeks, or others given eggplant, Tween 80, pancreatin concentrate, Resion or vitamin E.—D. Duncan.

SECKFORT, H. and ANDRES, E. Über den Fett-säuregehalt des Blutserums Gesunder. (Mit einem methodischen Erfahrungsbericht). [Fatty acid content of blood serum of healthy subjects. With a note on technique.] *Deutsch. Ztschr. Verdauungs- u. Stoffwechselerk.*, 1955, 15, 49-50. [Med. Klin., Johannes Gutenberg Univ., Mainz.]

Mean fasting values for fatty acids in the serum of 20 healthy subjects in m. equiv. per litre were 10.14 ± 3.11 for men and 7.29 ± 1.99 for women. The method was a modification of that of Stern and Shapiro (Abst. 3885, Vol. 23).—W. M. Deans.

5107

SAARINEN, P. On the nutritional factors affecting the level of volatile fatty acids in cows' peripheral blood. *Acta agral. fenn.*, 1955, 83, 133-146. [Dept. Animal Husb., Univ. Helsinki.] Finnish summary.

The total volatile fatty acid and cholesterol of the plasma of arterial blood of 18 Ayrshire cows at different stages of lactation were estimated at intervals during 4 months. The cows were divided into two groups, the one receiving 450 to 500 g. and the other 200 g. of crude fat daily. The ratio of both groups was varied in its fibre and protein content.

The volatile fatty acid of the blood increased with the fibre content of the ration with one variation, namely, temporary depression when the protein of the ration was high. The cholesterol of the blood usually varied inversely as the volatile acid.—A. T. Phillipson.

5108

GITTLEMAN, I. F., PINCUS, J. B., KRAMER, B., SOBEL, A. E. and SCHMERZLER, E. **Citric acid metabolism in infants during the neonatal period.** *Pediatrics*, 1955, 15, 124-134. [Dept. Paediat., Jewish Hosp., Brooklyn, N.Y.] Spanish summary.

Ca, P and citric acid levels in serum were estimated in 275 infants on the day of birth and the day of discharge from hospital, usually the fifth day. The infants were grouped according to diet, which was breast milk with or without vitamin D, or powdered milk mixtures differing in Ca:P ratio, with or without vitamin D.

In all 9 groups mean citric acid level fell significantly during the first 5 days of life. The fall was not related to Ca:P ratio, citric acid content of diet or vitamin D intake. Serum Ca levels fell in some infants. There was a positive correlation between citric acid and Ca levels in serum in 6 groups, the correlation being statistically significant in 4. There was a negative correlation in the remaining 3 groups.—F. C. Aitken.

5109

REDA, H. and SALEM, H. **Variation in the calcium and inorganic phosphorus contents of blood, urine and colostrum of Egyptian buffaloes and cattle associated with parturition.** *Indian J. Dairy Sci.*, 1955, 8, 19-25. [Fac. Agric., Univ. Cairo.]

Calcium and inorganic P were estimated in the serum, urine and milk of pregnant Egyptian buffaloes and cows fed on dry rations or green fodder. Diet caused significant differences in the serum and milk values, particularly of Ca.

In milk Ca and inorganic P were high at parturition, fell during the next 10 days and then remained constant. Serum Ca and P fell at parturition and then returned to pre-parturient levels. Urine values did not vary noticeably or regularly. The changes followed the same pattern in both cows and buffaloes.—T. D. Bell.

5110

SALEM, H. and REDA, H. **The study of inorganic phosphorus in blood in Egyptian buffaloes, native and cross breed cattle.** *Brit. Vet. J.*, 1955, 111, 260-263. [Fac. Agric., Univ. Cairo.]

Serum inorganic P in Egyptian buffaloes was higher than in Egyptian or crossbred cattle. There was little difference between the breeds of cattle. Values were higher in calves and heifers than in older stock, and in cattle they were higher in bulls than in cows. During pregnancy the tendency was the same in buffaloes and cows: there was a small regular increase until parturition, and at parturition values fell, rising to normal within a few weeks.—T. D. Bell.

5113

CANTARUTTI, F. and PANIZON, F. **Le modificazioni della cupremia nel periodo postnatale. [Changes in blood copper in the period just after birth.]** *Lattante*, 1954, 25, 721-723. [Clin. Pediat., Univ. Padua.] English summary.

Copper was estimated in the blood of infants from the first day of life to the second month. In $\mu\text{g. per } 100 \text{ ml.}$, the values for 13 specimens of umbilical cord blood ranged from 60 to 105, with only 2 values over 100. From 2 to 4 specimens tested on the 2nd, 3rd and 4th days the values were from 72 to 105, in the second week from 72 to 105, and subsequently from 98 to 130, with only one value below 100.—E. M. Hume.

LYMPH, CEREBROSPINAL FLUID, ETC.

5114

ROBINSON, D. S. **The chemical composition of chylomicro in the rat.** *Quart. J. Exp. Physiol.*, 1955, 40, 112-126. [Sir William Dunn Sch. Pathol., Oxford.]

Lipid particles from rat chyle, free from soluble lymph proteins, contained ether-soluble neutral fat, phospholipin and cholesterol, but no ether-insoluble nitrogen. The preparation, like whole chyle, was a stable emulsion and resisted the clearance of turbidity by pancreatic lipase. Both these properties were destroyed in the lipid particles and in whole chyle by pre-incubation with *Clostridium welchii* lecithinase and also in the lipid particles by incubation with normal plasma for 12 hr. After incubation with plasma the lipid particles contained phospholipin not extractable by ether and also some N in the aqueous residue. The stability of lipid particles in chyle was considered to depend on a phospholipin surface layer. A. Hepburn.

WALKER, B. S., TELLES, N. C. and PASTORE, E. J. **Amino-acids of the cerebrospinal fluid: normal paper chromatographic pattern and its duplication in multiple sclerosis.** *Arch. Neurol. Psychiat., Chicago*, 1955, **73**, 149-157. [Dept. Biochem., Sch. Med., Boston Univ., Mass.]

The free amino-acids of cerebrospinal fluid from patients with multiple sclerosis or similar neurological disease were not significantly different from normal.—A. Hepburn.

5116

HARRIS, W. H. and SONNENBLICK, E. H. **A study of calcium and magnesium in the cerebrospinal fluid.** *Yale J. Biol. Med.*, 1955, **27**, 297-303. [Clin. and Neuropathol. Lab., Connecticut State Hosp., Middletown.]

The cerebrospinal fluid of 40 patients without neurological disorder or psychosis or neurosis contained Ca 4.95 ± 0.11 and Mg 3.01 ± 0.06 mg. per cent., ratio Ca ions : Mg ions 1.64 ± 0.03 . In 10 similar patients the mean values were for cerebrospinal fluid 4.97 ± 0.01 , 3.14 ± 0.25 , 1.61 ± 0.07 , respectively, and for serum 9.97 ± 0.15 , 2.49 ± 0.18 and 4.1 ± 0.7 .

The constancy of the ratio Ca ions : Mg ions in cerebrospinal fluid suggests rigid control by some highly selective mechanism. There is evidence that the ratio may be different in patients with mental disturbance.—W. M. Deans.

TISSUES

5122

GARN, S. M. and HARPER, R. V. **Fat accumulation and weight gain in the adult male.** *Human Biol.*, 1955, **27**, 39-49. [Fels Res. Inst., Antioch Coll., Yellow Springs, Ohio.]

The results of X-ray measurements of subcutaneous fat thickness at 9 sites in 85 active men between 20 and 69 years (Abst. 5132, Vol. 24) were analysed according to age. All but anterior leg fat increased with age; iliac fat most of all, both absolutely and relatively. The changes in both fat thickness and bodyweight were most rapid between the third and fourth decades. The estimated weight of body fat, computed from

trochanteric fat, rose from 11.5 kg. in the third decade to 17.3 kg. in the sixth, or from 15.6 to 22 per cent. of bodyweight. All the fat thicknesses rose with the estimated weight of fat. The age changes corresponded closely to ordinary fattening; older men of average weight for age had the surface contours of younger men 5 kg. (7 per cent.) overweight for their age.

Over and above nutritional causes, decreased output of ketosteroids is suggested as a cause for fat deposition. It is pointed out that what is gained is not fat alone but fat-containing tissue, and that body fat also changes in composition with age.—W. M. Deans.

5123

BOLLIGER, A. and GROSS, R. **Non-keratins of avian and mammalian skin flakes.** *Austral. J. Exp. Biol. Med. Sci.*, 1954, **32**, 747-756. [Gordon Craig Res. Lab., Dept. Surg., Univ. Sydney.]

Total N.P.N. in skin flakes from mammals and birds was several times greater than in the corresponding hair or feathers. Ammonia was the greatest N fraction in mammals, but birds had most uric acid and no urea. Free amino-acids, at least 9 in number, increased after hydrolysis. Much of the non-keratin material was reducing in nature and increased after hydrolysis. Glucose and, after hydrolysis, arabinose, xylose and deoxyribose were identified chromatographically. Polysaccharides other than glycogen seemed to be present.—A. Hepburn.

5124

BOLLIGER, A. and GROSS, R. **Non-keratins of human head hair.** *Austral. J. Exp. Biol. Med. Sci.*, 1954, **32**, 739-745. [Gordon Craig Res. Lab., Dept. Surg., Univ. Sydney.]

The aqueous extract of human head hair from normal children and adults, hospital patients and cadavers was analysed for pentose, reducing substances, total N, NH_3 , amino-acids, urea and uric acid. Most samples had about the same amounts of pentose and reducing substances. The latter increased after hydrolysis in only 6 of 26 samples. Total N in normal subjects and in some patients was far below general mammalian levels. Some patients and children had higher than normal values. N was in greatest quantity as NH_3 . It rose proportionately with total N and was usually higher than urea N. Uric acid values were raised in moribund patients with chronic renal insufficiency and gout. Amino-acid N was about 10 to 20 per cent. of total N and frequently increased after hydrolysis.—A. Hepburn.

5125

COHEN, M. M. **Quantitation of phosphorus compounds in the normal and pathologic human**

brain. *J. Neuropathol. Exp. Neurol.*, 1955, **14**, 70-83. [Sect. Neurol., Veterans Admin. Hosp., Minneapolis, Minn.]

Inorganic, acid-soluble, lipid, nucleic acid and total P were estimated in 73 normal and pathological human brains and in 22 surgical specimens. Lipoid P decreased when there was demyelination. It was also present intracellularly. Deoxyribonucleic acid P increased greatly and ribonucleic acid P less in neoplasm or other cellular growth and both decreased in necrosis and other conditions producing a decrease of metabolising cells. Their ratio was a better indicator of tissue cellularity than acid-soluble P, which exhibited similar changes.—A. Hepburn.

5126

SETCHELL, B. P. and McCLEYMONT, G. L. **Depression in brain potassium in ovine pregnancy toxæmia.** *Nature*, 1955, **175**, 998. [Nutrit. Res. Lab., Vet. Res. Stat., Glenfield, N.S.W.]

The mean K content of slices of cerebral cortex from sheep dead of pregnancy toxæmia was significantly less than that of slices from normal sheep; that of slices from sheep dying from prolonged treatment with insulin was even lower. The values were 433, 388 and 314 millimoles K per kg. dry matter. The low blood sugar is thought to be responsible. The depression must be mainly in intracellular K. With whole brain, as opposed to cerebral cortex, no significant difference in K content was found.—D. Duncan.

5127

BRAASCH, J. W., ALBERT, A., KEATING, F. R. and BLACK, B. M. **A note on the iodinated constituents of normal thyroids and of exophthalmic goiters.** *J. Clin. Endocrinol.*, 1955, **15**, 732-738. [Lab. Endocrinol., Sect. Physiol., Mayo Clin., Rochester, Minn.]

A study of the distribution and turnover of I in the thyroids of 5 euthyroid subjects and 4 patients with exophthalmic goitre before and after I treatment showed no hitherto unknown iodinated compound in the patients. Unknown or abnormal compounds might nevertheless be present which could not be identified by the chromatographic method employed. The 4 patients were given by mouth 300 to 600 μCi . of ^{131}I . After 5½, 7½, 41 and 93 hr. biopsy specimens were taken from the thyroid of each patient. The patients were treated with Lugol's solution, 10 drops 3 times daily for 7 to 10 days. Subtotal thyroidectomy was then performed and second samples of each thyroid were obtained. The euthyroid controls, who were suspect of having tumours, were treated in a similar way. The mean percentage distribution of I in normal glands was thyroxine 35, triiodothyronine 8, diiodotyrosine 25 and

moniodotyrosine 17. The distribution in the glands before and after treatment was similar, but the rate of transfer of I to thyroxine was higher in the abnormal glands. Iodine treatment seemed to slow the formation of thyroxine, after which involution of the gland occurred.—B. W. Simpson.

5128

CALET, C. and JACQUOT, R. Influence de l'aureomycine sur la composition corporelle du Rat blanc. [Effect of aureomycin on the composition of the body of the white rat.] *C.R. Acad. Sci.*, 1955, **240**, 1370-1372.

Previous work (Abst. 3102, Vol. 24) suggested that the improved weight gains of rats given aureomycin were due to deposition of fat. This was confirmed by analysis of the carcasses of young rats from groups given a basal diet low in protein, 10.5 per cent., but otherwise adequate, of white flour 85, oil and margarine 8, salt mixture 4 and cellulose 2 per cent., and optimum amounts of all known vitamins, with or without 100 mg. aureomycin per kg. Growth on these diets was much slower than normal. Rats not given aureomycin were killed at 54 g.; those given aureomycin then weighed 70.2 g. For comparison, carcasses of rats of about those weights which had had a balanced diet were analysed also. At the lower weight there was no difference in carcass composition, but at the higher weight rats on the basal diet with aureomycin contained significantly more fat and less protein than those on the balanced diet. For the same amount of food consumed rats on the basal diet with aureomycin elaborated 3 times as much fat as those on the basal diet only. W. M. Deans.

5129

MARCH, B. and BIELY, J. Fat studies in poultry. 4. The effect of Triton WR-1339 on tissue lipid levels in cockerels. *Poultry Sci.*, 1955, **34**, 293-295. [Poultry Nutrit. Lab., Univ. British Columbia, Vancouver 8.]

For part 3 see Abst. 4939, Vol. 25.

A single subcutaneous injection of Triton WR-1339, a surface-active agent, produced a temporary rise in blood fat in cockerels. Repeated injections at 6-day intervals maintained blood fat at a high level. Liver fat was increased from 12 to 19 per cent. and tibial muscle fat decreased from 10 to 5.6 per cent. The weight of depot fat fell from 5.1 g. to 0.7 g.—J. S. Thomson.

5130

COLLINS, F. D. and WHEELDON, L. W. Chromatography of phospholipids. *Nature*, 1955, **175**, 772-773. [Dept. Biochem., J. Curtin Sch. Med. Res., Australian Nat. Univ., Canberra.] In a typical experiment fat was extracted from the liver of a rat 1 hr. after it had received an

intravenous injection of 0.8 mC. $\text{NaH}^{32}\text{PO}_4$. The fat was treated in benzene with fluoro-2:4-dinitrobenzene in the presence of triethylamine. The dinitrophenyl-lipid was then methylated with diazomethane and the product was chromatographed. Four main fractions were eluted and were distinguished by their absorption spectra: (1) light petroleum eluted glycerides and vitamin A; (2) benzene or benzene-chloroform mixtures removed a fraction showing λ_{max} at 328 m μ (light petroleum), which further chromatography showed to consist of a mixture of phospholipins containing ethanolamine and serine; (3) chloroform containing 10 per cent. ethanol eluted material showing λ_{max} 345 m μ (light petroleum), which further chromatography revealed to be a mixture of cephalins and lecithins which varied in radioactivity; and (4) ethanol alone removed predominantly choline-containing phospholipins.

It is concluded that in addition to phosphatidyl serine, phosphatidyl ethanolamine, phosphatidyl choline and traces of sphingomyelin and inositol phospholipins, phospholipins probably contain additional, as yet unidentified, molecular species.

G. A. Garton.

WHITE, H. L. and ROLF, D. Whole tissue electrolyte analyses in normal and adrenalectomized rats. *Amer. J. Physiol.*, 1955, **180**, 287-295. [Dept. Physiol., Sch. Med., Washington Univ., St. Louis, Mo.]

There were 4 groups of rats. A control group of 15 was fed to appetite and rats were killed at a weight of about 225 g. A group of 5 was restricted to the amount eaten by a third group of 7, from which adrenals were removed; they were killed from 5 to 7 days after restriction of feeding or operation. Rats in the fourth group of 8 were killed from 12 to 22 days after removal of adrenals, during which time no or only inadequate treatment with adrenal cortex hormone was given. After preparation by methods described in detail estimations were made of Na, K, Cl, water and fat-free solids in skeletal muscle, skin, viscera, skeleton and blood. Mean results with standard deviations are tabulated for total amounts of these constituents per kg. fresh tissue and for total amounts of tissue and of constituents per rat of original weight 250 g. Additional calculated data on extra- and intra-cellular water and on amounts of electrolytes per 100 g. fat-free solids are also presented.

Physico-chemical equilibria in extra- and intracellular fluids in different tissues are discussed. The losses, in m. equiv., of Na 2.67, K 1.2 and Cl 1.75 by a rat weighing 250 g. in the 5 days after adrenalectomy agree with data from balance experiments. The findings for Na and Cl in skeleton and for Na in muscle do not support the view that the fall of concentration which occurs in these elements in extracellular fluid after adrenalectomy results from their being deposited in the bone or muscle cells. The methods of estimating extracellular fluid *in vivo* are thought not to be sufficiently accurate for measuring changes in concentrations of electrolytes which follow adrenalectomy.

D. Harvey.

5133

UJEWSKI, L. and GLEGG, R. E. **Carbohydrates in thyroglobulin and the lens capsule.** *Canad. J. Biochem. Physiol.*, 1955, **33**, 199-201. [Dept. Anat., McGill Univ., Montreal, Que.]

The carbohydrate content of thyroglobulin from thyroids and of the lens capsule from eyes of cattle was estimated qualitatively by the paper chromatography of hydrolysates. Quantitative estimations were made by the carbazole and sulphuric acid technique. Thyroglobulin contained 4.2 per cent. carbohydrate, made up of galactose, mannose and fucose; the lens capsule 11.8 per cent., made up of galactose, glucose, mannose and fucose.

G. F. Garton.

ENGFELDT, B. and HJERTQVIST, S. O. **Biophysical studies on bone tissue. 15. A histochemical and microradiographic study on normal bone tissue.** *Acta pathol. microbiol. scand.*, 1955, **36**, 385-390. [Dept. Phys. Cell. Res., Karolinska Inst., Stockholm 60.]

For part 10 see Abst. 2409, Vol. 25.

In bone tissue from a young dog, thin sections studied by microradiography showed narrow zones round Haversian canals which had very low X-ray absorption. These zones were shown histochemically to contain acid mucopolysaccharides and may represent an accumulation of chondroitin sulphate.—D. Duncan.

5135

CAGLIOTI, V., ASCENZI, A. and SCROCCO, M. **Le relazioni tra sostanza organica e inorganica**

nel tessuto osseo studiate mediante spettrofotometria nell'infrarosso. [The relations between organic and inorganic substances in bone tissue studied by infrared spectrophotometry.] *Arch. Sci. biol., Bologna*, 1955, **39**, 116-126. [Ist. Chim. Gen. (Centro del C.N.R.), Univ. Rome.]

Sections of compact bone were prepared from the femoral diaphysis of cattle. The sections of whole bone were about 10 μ . thick and 25 mm. in diameter; the technique of cutting and mounting in Canada balsam is described. The osseous sections were demineralised in 2 per cent. HNO_3 and those without organic matrix were obtained by boiling in 6 per cent. KOH. The latter were so fragile that the spectrographic study was made on powder instead of on true sections.

The infrared absorption spectra of the 3 types of preparation are shown. It is concluded that in whole bone there is a bond between the $-\text{SO}_2-$ group in the ossein and the $-(\text{PO}_4)^{3-}$ group in hydroxyapatite.—D. Duncan.

5136

BRUDEVOLD, F. and STEADMAN, L. T. **A study of copper in human enamel.** *J. Dent. Res.*, 1955, **34**, 209-216. [Eastman Dent. Dispensary, Univ. Rochester, N.Y.]

The range of Cu in 4 successive layers of the enamel of pooled fully erupted teeth was from 15 to 30 p.p.m., with an average of 20 p.p.m. The distribution in the layers was random and was unaffected by age. In impacted teeth the average value was about 7 p.p.m. and in fluorosed teeth the range was from 6 to 12 p.p.m. Individual teeth showed wide variation in Cu content of the enamel, but there was no correlation between Cu content and pigmentation or caries.—J. S. Thomson.

Cold and its effect on concentration of phosphorus and the incorporation of labelled inorganic phosphate into the inorganic P of the plasma and the adrenal inorganic P, 20-min. hydrolysable P, and total acid-soluble P were studied in rats.

Short periods of cold, up to 24 hr., increased the relative specific activity of each of the adrenal fractions, but not that of the inorganic P of the plasma. Longer periods of cold, up to 16 days, increased adrenal weight and also the relative

specific activity of each of the 3 acid-soluble P fractions of the adrenal. Increased specific activity was not due to decreased concentration of P in any of the fractions.

Evidence is given for the view that an increased rate of passage of ^{32}P across the cell membrane accounts for this change and that adrenocorticotrophic hormone is responsible for the more rapid changes. It is suggested that changes after longer exposures may be related to thyroid function.

Soc. ital. Biol. sper.*, 1953, **29**, 1769-1771. [Ist. Fisiol., Univ. Palermo.]

In continuation of previous studies (Abst. 4493, Vol. 23), 4 groups of 5 rats weighing about 200 g. were subjected to partial starvation, being given daily 0.17 or 0.18 Cal. per g. bodyweight of a complete diet. The groups were given on alternate days saline or an extract of thymus or of adrenal or of anterior pituitary. All the groups except those given thymus died after mean times of from 61.2 to 64.6 days, with percentage weight losses of from 50.6 to 51.3. For those given thymus the mean values were 56.8 days and 53.0 per cent.

- HODGES, R. E., EVANS, T. C., BRADBURY, J. T. and KEITTEL, W. C. **The accumulation of radioactive iodine by human fetal thyroids.** *J. Clin. Endocrinol.*, 1955, **15**, 661-667. [Dept. Int. Med., State Univ. Iowa, Iowa City.]

The human foetal thyroid begins to accumulate ^{131}I at about the twelfth week of gestation. Foetuses from 9 pregnancies, ranging from 6½ to 15 weeks, were studied after 500 μC . of ^{131}I had been given about a day before surgery. Maternal thyroid uptake was then studied and the thyroids

of the foetuses were examined by histology and by radio-autography. There was ^{131}I in all but 3 of the 9 foetuses. Doses of stable I had been administered previously to the mothers of 2 of these 3, and it is presumed that this prevented the accumulation of ^{131}I by the maternal and foetal thyroids. The third foetus was only 6½ weeks of age and the thyroid was in its primitive form. These 9 patients were euthyroid, but 1 thyrotoxic patient who had been pregnant 19 weeks received 6100 μC . of ^{131}I . She retained 69 per cent. of the dose at the end of 24 hr. A normal child was born which, 1 year later, was normal in height and weight and in good health. In thyrotoxicosis the maternal thyroid collects more I than is normal and this probably reduced the amount available to the foetus.—B. W. Simpson.

BISHOPRIC, G. A., GARRETT, N. H. and NICHOLSON, W. M. The thyroidal uptake of radioactive iodine as modified by an iodine-restricted diet. *J. Clin. Endocrinol.*, 1955, 15, 592-597. [Dept. Med., Sch. Med., Duke Univ., Durham, N.C.]

Twenty patients who were being treated with the Kempner rice diet and 125 patients not receiving this diet were given a tracer dose of 20 μC . of ^{131}I . After 24 hr. the percentage of the dose present in the thyroid was estimated by scintillation counter.

The normal range of uptake of ^{131}I was taken as 15 to 45 per cent. of the dose. Of the patients not receiving rice diet 92 per cent. had normal I uptakes, 6.4 per cent. had less, 1.6 per cent. had more. Of the 20 patients on the rice diet half had uptakes of 46 per cent. or more. Twelve of these patients had been on the rice diet for 2 or more years; of these 8 had uptakes of 46 per cent. or more. Of 8 patients on the rice diet for 3 months or less only 1 had a thyroid ^{131}I uptake greater than 45 per cent. It is suggested that the avidity of the thyroid for I in many patients who had been on a rice diet for a long time was a deficiency phenomenon, though no enlargement of the thyroid was associated with it.—B. W. Simpson.

LAAKE, H. Osteoporosis in association with thyrotoxicosis. *Acta med. scand.*, 1955, 151, 229-235. [Dept. B., Med. Univ. Clin., Rikshosp., Oslo.]

Osteoporosis was found in 7 out of 17 thyrotoxic patients, but there was no correlation between the degree and duration of the thyrotoxicosis and the skeletal changes. The Ca and P contents of the serum were normal and in only 1 patient was there a high phosphatase level.

Under treatment with Tapazole (1-methyl-2-mercaptoimidazol) the phosphatase became normal and the osteoporosis improved. Ca and N balances in 5 patients were positive, and in the 7 patients with negative balances 5 improved under Tapazole treatment.

In thyrotoxicosis the increased N breakdown may prevent normal formation of bone matrix, but it is suggested that there may be a combination of thyrotoxicosis and post-climacteric conditions which induce osteoporosis, as most patients were over 50.—B. W. Simpson.

HULL, O. H. Critical analysis of two hundred twenty-one thyroid glands: study of thyroid glands obtained at necropsy in Colorado. *Arch. Pathol.*, 1955, 59, 291-311. [Dept. Pathol., Univ. Colorado Sch. Med., Denver.]

During 1952 and 1953, 221 thyroid glands from necropsies in the Colorado General Hospital were examined from settlers who had dwelt for some time in the Rocky Mountain area, a high, fresh-water, potentially goitrous region. Normal thyroids weighed on the average 19.3 g. in the males and 17.7 g. in the females and were 35.7 per cent. of the total. The incidence of nodules was 62.2 per cent. in males and 67.0 per cent. in females. Nodules were infrequent at younger ages, but common in the older people. Three primary carcinomas were found, all in multi-nodular glands. Cancers metastatic to the thyroid were found in 16.9 per cent. of the patients who had died of cancer. Pyramidal or third lobes were found in 48.9 per cent. In 5.9 per cent., parathyroids were found buried within the thyroid tissue.

STRISOWER, B., GOFMAN, J. W., GALIONI, E., RUBINGER, J. H., O'BRIEN, G. W. and SIMON, A. Effect of long-term administration of desiccated thyroid on serum lipoprotein and cholesterol levels. *J. Clin. Endocrinol.*, 1955, 15, 73-80. [Donner Lab., Div. Med. Physics, Univ. California, Berkeley.]

The serum lipoproteins of low density, S_f 0-12 and 12-20, from 50 otherwise healthy schizophrenic patients were significantly reduced after 3 weeks when 3 grains of thyroid were given daily. The higher the initial value, the greater the fall. Lipoproteins S_f 0-12 then rose steadily to about the initial value after 24 weeks and were little changed after 33 weeks. Serum cholesterol showed a similar trend. Lipoproteins S_f 12-20 rose slightly but were well below the initial value after 33 weeks. Lipoproteins S_f 20-100 and S_f 100-400 were not significantly altered by the administration of thyroid for 33 weeks.—A. Hepburn.

AXELRAD, A. A., LEBLOND, C. P. and ISLER, H. Role of iodine deficiency in the production of goiter by the Remington diet. *Endocrinology*, 1955, 56, 387-403. [Dept. Anat., McGill Univ., Montreal.]

Components of the Remington low-iodine diet (Abst. 645, Vol. 7) were tested to see if the goitrogenic effect could be attributed to one ingredient. It was shown that the goitre-producing action was due to the low I content, 4.1 μ g. per 100 g., aggravated by inclusion of NaCl. The average weight of the left lobe of the thyroid of mice on the diet without NaCl was 2.3 mg., that of mice receiving 1 per cent. NaCl was 12.0 mg., but body-weights were equal. Mice can survive on as little as 60 μ g. NaCl daily. The concentration of radio-active I in the thyroids was assessed with a Geiger counter in mice given 2 μ C. radio-active I subcutaneously and killed 2½ hr. later. It was higher in mice given NaCl.

In another experiment 109 male mice were divided into 4 groups. One group was given a diet of glucose, wheat gluten, yeast and CaCO₃, containing 4.1 μ g. I per 100 g. diet, and the other 3 groups received added KI to raise the I content to 12.2, 32 and 100 μ g. per 100 g. Each group was divided into 4 sub-groups which received 0, 0.1, 1.0 or 3.0 g. NaCl per 100 g. diet. The mice were injected with radio-active I and killed on the 68th and 69th days. The mice on the lowest I intake had the largest thyroids and the highest concentration of radio-active I. The size of the glands and the concentration of radio-active I increased with increasing NaCl in the diet. In the groups getting KI, the thyroids were small. Although the concentrations of radio-active I were inversely related to the amounts of added KI, the concentrations increased with increasing percentages of NaCl, and examination of the right lobes showed increase of activity with increasing amounts of NaCl.

The goitrogenic effect of NaCl was basically different from that of antithyroid substances, which generally prevent the formation of thyroid

hormone. The presence of NaCl maintained or enhanced the function of the thyroid and thereby increased the I required for the production of hormone.—B. W. Simpson.

GÓTH, A., LENGYEL, L., BENCZE, E., SÁVELY, C. and MAJSAJ, A. The role of amino-acids in inducing hormone secretion. *Experientia*, 1955, 11, 27-29. [Margit Hosp., Budapest.]

Low eosinophil counts occurred 4 hr. after the taking of egg white or amino-acids in healthy men but not in those with Addison's disease. In normal rats leucine, methionine, valine, phenylalanine and tryptophan, but not glycine, histidine or isoleucine, produced low eosinophil counts not found in adrenalectomised rats. Serum taken from normal men and patients with anterior pituitary deficiency 4 hr. after they had eaten egg white was injected into normal and adrenalectomised rats. Only the normal serum increased the blood sugar in normal rats and reduced the eosinophil count in those adrenalectomised.

Injection of valine or leucine into rats caused loss of ascorbic acid from the adrenals, attributed to mobilisation of the rats' own adrenocorticotrophic hormone from the pituitary. Daily injection for 10 days of 0.02 g. valine, leucine, tyrosine or methionine, but not of glycine, into immature female rats resulted in increased weight of the ovaries and uterus, and bleeding follicles of the ovaries and oedematous swelling of the uterus.

It is suggested that the specific dynamic action of foods may be explained by an acute stimulating effect on the pituitary.—C. Warner.

FÖRSTER, W., HERRMANN, C., SCHARF, J. H. and EHRENBREND, F. Korrelationen zwischen Stoffwechsel-, Schilddrüsen- und Hypophysenveränderungen bei Ratten nach chronischer Verabreichung von NaI, BAL und Methionin. [Relations between changes in metabolic rate, thyroid and pituitary in the rat after prolonged administration of NaI, BAL and methionine.] *Arch. exp. Pathol. Pharmacol.*, 1955, 225, 195-209. [Pharmakol. Inst., Univ. Mainz.]

Groups of young rats weighing about 100 g. received for 46 days a stock diet, and in addition

daily, in mg. per kg. bodyweight, NaI 250 or 1000 or methionine 3000 or both, by stomach tube, or BAL 15 by intramuscular injection in olive oil, or NaI and BAL. Controls received saline. Six rats of each group were used for B.M.R. estimations twice weekly. One from each group was killed after 4, 7, 11, 13, 18 and 35 days for histological study of thyroid and pituitary.

B.M.R. in the control group varied very little in the course of the experiment. With NaI there was a sharp fall, a rise to well above normal, a second fall equal to the first and a final rise. With NaI and methionine the changes were similar but occurred somewhat later, and with NaI and BAL they were yet further delayed and of smaller magnitude.

The thyroid showed no significant change in weight in any group, but histologically showed increased activity when B.M.R. was low and low activity when B.M.R. was high. The proliferation of the thyroid was accompanied by increases of the beta cells in the pituitary and vacuolisation. Increased B.M.R. was accompanied by an increase in colloid and in beta cells with dense beta granulation.

The mechanisms concerned are discussed.

GREENBERG, S. M. and ATERMAN, K. **Thyroid-cortisone "antagonism" in rats as measured by growth, organ weights and food utilization.** *Metabolism*, 1955, 4, 264-274. [Dept. Pharmacol., Med. Sch., Univ. Birmingham.]

The effects of the prolonged administration of cortisone and of thyroid hormone, singly and together, on growth, food intake, food utilisation and organ weights were studied. Doses of 1.5 or 1.25 mg. cortisone were injected subcutaneously 6 days a week. Dried thyroid formed 0.05, 0.10, 0.20 or 0.40 per cent. of the diets. Male rats of weight 45 to 55 g. were used and the tests lasted 4 or 5 weeks. Organ weights were recorded at the end.

When cortisone alone was given, growth was retarded and food intake as well as efficiency of utilisation of food were reduced. Dried thyroid also reduced growth except when the fat content of the diet was high, 10 per cent., and the level of dried thyroid in the diet was as low as 0.10 per cent.; 0.4 per cent. dried thyroid with 10 per cent. fat retarded growth. The rats receiving thyroid ate as much as or more than their controls, but efficiency of utilisation fell as the level of thyroid rose. When cortisone and thyroid were given together, the growth-inhibiting property of the cortisone was reduced and there was an increase of food consumption and an increased efficiency of food utilisation except at the highest level of thyroid, 0.4 per cent., in which group mortality was very high. Adrenals did not atrophy and there was no involution of thymus or spleen, but heart and kidney weights increased, the effects of the 2 substances being additive.

BROZEK, J. and GRANDE, F. **Body composition and basal metabolism in man: correlation analysis versus physiological approach.** *Human Biol.*, 1955, 27, 22-31. [Lab. Physiol. Hyg., Univ. Minnesota, Minneapolis.]

The physiological approach to the relation between body composition and B.M.R. has been made by direct measurement of oxygen uptake of different organs *in vivo* and evaluation of their share in the basal oxygen consumption of the whole body. The method of using correlation analysis to estimate the B.M.R. from body measurements is discussed and it is found that partition of the B.M.R. between tissues as estimated on the basis of direct measurements is different from that inferred from correlation analysis. For instance, "active tissue mass" as estimated from body-weight minus the weights of fat, bone mineral and extracellular fluid is sometimes a useful concept, but it cannot be identified with the muscle mass,

and the share of the skeletal muscle in the total oxygen consumption is probably not much more than 25 per cent. Moreover, despite the highly significant correlation between extracellular fluid and B.M.R. which indicates that the fluid compartment "accounts" for 64 per cent. of the variation in B.M.R., the actual participation of the fluid in total oxygen consumption must be negligible.

DOLE, V. P., SCHWARTZ, I. L., THORN, N. A. and SILVER, L. The caloric value of labile body tissue in obese subjects. *J. Clin. Invest.*, 1955, 34, 590-594. [Hosp. Rockefeller Inst. Med. Res., New York.]

Five obese women were given a diet of evaporated milk, maize oil, glucose and water. For the first 2 to 3 weeks of the study the amount was adjusted approximately to maintenance value for each patient.

There followed 4 periods of 8 days in each of which 55 g. (485 Cal.) was subtracted from the daily maintenance amount during half of the period and was added to the maintenance amount during the other half. Bodyweights were recorded daily. From statistical analysis of the data it was computed that the average energy equivalent of weight lost or gained was 2.5 Cal. per g. and the average daily energy expenditure 20.2 to 24.4 Cal. per kg.

DURNIN, J. V. G. A. The oxygen consumption, energy expenditure, and efficiency of climbing with loads at low altitudes. *J. Physiol.*, 1955, 123, 294-309. [Inst. Physiol., Univ. Glasgow.]

The subjects were 2 men in good physical condition, 32 and 22 years old, 173 and 178 cm. in height, weighing 81 and 86 kg. and with B.M.R. of 1.10 and 1.41 Cal. per min. They climbed on 2 slopes of Ben Lomond which had mean gradients of 1 in 5.7 and 1 in 4.7, at controlled rates of vertical climb of 600 and 630 metres per hr. and rates of linear climb of 2.1 and 1.8 m.p.h. Loads carried were 5, 10, 15 and 20 kg., the smallest load representing the Max Planck respirometer and a frame. The experiment was planned as an 8 × 8 Latin square: the variables were days, loads, gradients, subjects and the sequence in which loads were carried.

Mean oxygen consumption with different loads and gradients varied from 2.22 to 2.60 litres per min. in the older and from 2.09 to 2.69 in the younger subject, with a significant difference between subjects and a highly significant difference between loads and also between days. Mean energy expenditure was from 11.09 to 13.25 and from 10.42 to 13.45 Cal. per min. in the 2 subjects. Mean pulmonary ventilation was from 49.32 to 68.01 and from 50.85 to 62.18 litres per min., and mean oxygen extraction from 5.37 to 4.64 and from 4.94 to 5.18 per cent. There was a negative correlation between oxygen extraction and

ventilation, although the mean oxygen extraction of the second subject showed an almost steady increase as the load became greater.

The efficiency of climbing, measured as the gross weight \times vertical height climbed, in kg. m. per min., \times the correction factor, divided by the difference between energy expenditure in climbing and the B.M.R., differed little with load. When basal metabolism was deducted the greatest efficiency reached by the older subject was on the lower gradient with the greatest load and was 23 per cent.; by the younger subject it was on the same gradient with a load of 5 kg., and was 26 per cent. When the metabolism of horizontal walking was deducted the greatest mean efficiencies were 32 and 36 per cent.

The subjective feelings of the subject often did not agree with the physiological findings.

MÜLLER, E. A. Wirkungsgrad und Leistungsfähigkeit bei Arbeit mit den Wadenmuskeln. [Effort and work capacity with the calf muscles]. *Internat. Ztschr. angew. Physiol. Arbeitsphysiol.*, 1955, 16, 25-34. [Max Planck Inst. Arbeitsphysiol., Dortmund.]

A foot ergometer is described which measures work of the extensor muscles, the axis of which passes through the ankle. Only the calf muscles are used. Work can be kept up for as much as 8 hr. by a man of medium strength without much affecting the pulse frequency. A bicycle based on the same principle required about as much energy to cover a given distance as an ordinary bicycle and much less energy than walking, and for a given expenditure of energy its velocity was between those of walking and the ordinary bicycle.

NUKADA, A. and MÜLLER, E. A. Hauttemperatur und Leistungsfähigkeit in Extremitäten bei dynamischer Arbeit. [Skin temperature and work capacity in the limbs during active work.] *[Internat. Ztschr. angew. Physiol. Arbeitsphysiol.]*, 1955, 16, 61-73. [Max Planck Inst. Arbeitsphysiol., Dortmund.]

With the ergometer described in the preceding Abst. it was shown that the colder the skin of the leg, the longer is the maximum working time of the calf muscles at constant output and the lower the pulse rate during work and recovery. The difference in work capacity was inversely related to blood flow in the superficial vessels.

NUKADA, A. Die Muskelleistungsfähigkeit bei reaktiver Hyperämie der Muskeln. [Work capacity during reflex hyperaemia of the muscles.] *Internat. Ztschr. angew. Physiol.*

Arbeitsphysiol., 1955, 16, 81-82. [Max Planck Inst. Arbeitsphysiol., Dortmund.]

In 2 men the capacity for severe work on the foot ergometer was increased during the period of reactive hyperaemia after the leg had been constricted to reduce circulation.—D. Duncan.

5174

NUKADA, A. Hauttemperatur und Leistungsfähigkeit in Extremitäten bei statischer Haltearbeit. [Skin temperature and work capacity in the limbs during static postural work.] *Internat. Ztschr. angew. Physiol. Arbeitsphysiol.*, 1955, 16, 74-80. [Max Planck Inst. Arbeitsphysiol., Dortmund.]

The work capacity was estimated from the ability of the subject to keep his arm bent at a right angle while a weight was hung from the wrist. Warming the arm by diathermy or in a water-bath before work reduced the time for which loads could be supported, and cooling the arm increased it. The effect was not closely related to the muscle temperature, but appeared to depend on the circulation, which was greater in the muscle when driven away from the skin and vice versa.—D. Duncan.

5175

LEROY, A. M. Utilisation de l'énergie des aliments par les animaux. [Utilisation of feed energy by animals.] *Ann. Zootech.*, 1954, 3, 337-372. [Dept. Zootech., Inst. Nat. Agronom., Paris.]

Data from 337 experiments on energy metabolism for 6 species were obtained from work published by 12 groups of authors. The heat loss in 24 hr. by a normally fed animal in conditions of equilibrium is equal to the maintenance expenditure plus K times the energy of the absorbed food in terms of dry matter. The coefficient K measures the specific dynamic action of the food and in all the species considered it is about 1 Cal. per g. dry matter. In cattle and pigs there is a positive correlation between the value of K and the ratio of total net energy expenditure to maintenance expenditure. There is considerable individual variation in K, which indicates that within a species there are animals which utilise food well or badly. K tends to be less when the animal consumes its ration quickly.—D. Duncan.

LEROY, A. M. and ZELTER, S. Z. Contribution à l'étude des échanges énergétiques du mouton. [Study of the energy exchange of sheep.] *Ann. Zootech.*, 1954, 3, 373-385. [Lab. Recherches Zootech., Inst. Nat. Agronom., Paris.]

Respiratory exchange and N balance were studied in sheep of different ages, in relation to the time of feeding.

The energy lost during consumption and digestion of feeds, as shown in the previous Abst., is approximately equal to 1 Cal. per g. dry matter ingested. When an animal is in energy equilibrium,

Metabolisable energy = $E + P + Ms \times 1 \text{ Cal.}$,

where E is maintenance energy, P is productive energy and Ms the dry matter of the ration. Practical application of the findings is discussed.

MILOSAVLJEVIĆ, S. and ŠEKOVIĆ, N. Prilog poznavanju radne sposobnosti brdskog konja sa Peštera. [Working capacity of the Pešter mountain horse.] *Acta vet., Belgrade*, 1954, 4, No. 4, 83-87. [Inst. Biol. Gajenja, Vet. Fak., Belgrade.] German summary.

The horses studied were 13 geldings and 7 mares aged from 4 to 22 years, and about 131.5 to 135.6 cm. [51 to 53 in.] high at the shoulder. [They were not weighed.] The work consisted in carrying a load of 100 kg. on a pack saddle weighing another 15 kg. for 10,000 m., which took 2 hr.

The average length of step was 144 cm. in the first 100 m. and 142 in the last, and the times taken for each step were 1.03 and 1.05 sec. The pulse rate was 43.55 per min. before and 48.05 after work and 46.25 after a 20-min. rest. Respiration rates at the same times were 20.8, 34.8 and 22.8. There was no change of temperature. Hb increased during work by 10.9 per cent., red cell count by 11.6 per cent. and white cell count by 10 per cent. The seven oldest horses, over 12 years old, took slightly longer to cover the distance and showed greater changes in pulse rate and blood picture than the younger ones.—D. Duncan.

5178

MORRISON, S. D. The total energy metabolism of non-pregnant rats. *J. Physiol.*, 1955, 127, 479-497. [Inst. Physiol., Univ. Glasgow.]

A closed-circuit respiration calorimeter, which is described, was used to study the metabolism of adult female rats in periods of 2 to 5 days, the latter covering the complete oestrus cycle. The rats weighed 100 to 250 g. and were fed to appetite on the Bruce and Parkes diet 41 (Abst. 5251, Vol. 19). Energy expenditure was calculated from oxygen consumption, CO_2 production and urinary N output, and water exchange was measured.

The total energy expenditure varied linearly with bodyweight and net energy intake. It was estimated to be 153 per cent. of the B.M.R. The mean non-protein R.Q. was 0.97, closely corresponding to the value of 0.955 expected from the composition of the diet. R.Q. varied linearly with the ratio of ingested energy to energy expenditure and the ratio of absorbed energy to energy expenditure. There was usually, but not invariably,

a diurnal variation in total energy expenditure, which on the average was highly significant, with maximum oxygen consumption between 10 p.m. and 6 a.m. and minimum from 2 to 6 p.m. The total mean variation was 10.5 per cent. Considerable activity with much eating occurred during the night and again between 10 a.m. and 2 p.m. In rats studied for 5 days there was a tendency to higher energy expenditure in pro-oestrus and late di-oestrus, but the differences were not significant.

The total evaporated water showed a large variation from day to day, apparently independently, for any rat or period, of other metabolic measurement such as total energy expenditure. There was no significant variation with bodyweight. The mean water evaporation was estimated to be 13.6 g. daily with a coefficient of variation of 11 per cent. From the ventilation rate and other factors it was calculated that of the total evaporation 17 per cent. was of pulmonary origin in rats weighing 100 g., and 32 per cent. in rats weighing 250 g. If the latent heat of evaporation from the rat under the given conditions were 0.58 Cal. per g., the mean total evaporative heat loss was 7.9 Cal daily, and for rats of 100 and 250 g., 32 and 18.6 per cent. of the total daily energy expenditure.—D. Duncan.

GLEISS, J. and WEBER, H. G. Beiträge zum Frühgeborenenproblem der Gegenwart. 8. Die Entwicklung der Wärmeregulation von Frühgeborenen im Vergleich zu Neugeborenen. [The problem of the premature baby. 8. The development of heat regulation in premature as compared with [term] newborn infants.] *Ztschr. Kinderheilk.*, 1955, 76, 138-147. [Kinderklin., Med. Akad., Düsseldorf.]

For Nos. 7, 9 and 10 in this series see Absts. 5494, 5495, Vol. 25.

Thermo-electric measurements of skin and rectal temperatures in 14 premature infants, birthweights 1120 to 2070 g., and 14 infants of birthweight 2640 to 4100 g., showed that the premature are to some extent poikilothermic. The development of heat regulation is gradual and independent of birthweight and weight gain. Prematures require a higher environmental temperature to maintain the same rectal temperature as term infants, but the relation of rectal to bed temperatures is similar. From this the conclusion is drawn that it is chiefly the regulation by control of peripheral circulation that is defective in the premature infant.—I. Leitch.

MEEHAN, J. P. Body heat production and surface temperatures in response to a cold stimulus.

J. Appl. Physiol., 1955, **7**, 537-541. [Arctic Aeromed. Lab., Ladd Air Force Base, Alaska.]

The subjects were 9 Alaskan natives aged from 17 to 26 years and 8 Caucasian subjects aged from 21 to 26 who had spent at least a year in Alaska. All were fed for at least 2 days before the experiment on standard mess rations.

The B.M.R. of all the subjects was normal. In a cold room at 6° to 7° C. the native subjects increased their metabolic rate in 90 min. much more than the Caucasians; the increases were 142 ± 22 and 77 ± 11 per cent. This was ascribed to greater shivering on the part of the natives. They kept their hands and feet warmer, but mean body and trunk temperatures did not differ significantly from those of the Caucasians. At the end the native subjects showed a fall in rectal temperature and the Caucasians a rise.

BEAKLEY, W. R. and FINDLAY, J. D. **The effect of environmental temperature and humidity on the respiration rate of Ayrshire calves. The effect of environmental temperature and humidity on the frequency of the heart beat of Ayrshire calves.** *J. Agric. Sci.*, 1955, **45**, 452-460; 461-468. [Hannah Dairy Res. Inst., Kirkhill, Ayr.]

The respiration rates of 3 pairs of 4-month-old Ayrshire bull calves were measured in a holding room; 1 animal of each pair was then transferred to a hot room and exposed for 6 hr. on different days to 15°, 20°, 25°, 30°, 35° and 40° C. dry bulb temperature at 17 mg. per litre absolute humidity and to temperatures of 30°, 35° and 40° C. at 7 mg. per litre saturation deficit.

Respiration rates increased with increasing environmental temperature and humidity. Changes in respiratory rate at high and low humidities followed the same pattern, but the values obtained at high humidity were higher and suggested that temperatures of 30° and 35° C. at high humidity had the same effect on respiration rate as temperatures of 33° and 46° C. at low humidity. At high temperature and humidity respiration rate reached a maximum and then fell. The decline coincided with an increase in the amplitude of flank movements. It was suggested that the fall in respiration rate with time of exposure was associated with a decline in the CO₂-combining capacity of the blood.

Heart rates increased with increasing environmental temperature above 20° C. and with increas-

ing humidity above 30° C. High humidity at 40° C. increased the heart rate by 48, 108 and 136 beats per min. in the 3 calves. There was a decline in heart rate with increasing exposure to temperatures above 25° C. The heart rates of the control calves reached a maximum 2 hr. after feeding and then declined. It was concluded that heart rate is an unreliable index of heat tolerance in young cattle.—J. N. Aitken.

5183

KLEMM, G. H. and ROBINSON, K. W. **The heat tolerance of two breeds of calves from 1 to 12 months of age.** *Austral. J. Agric. Res.*, 1955, **6**, 350-364. [Sir William Macgregor Sch. Physiol., Univ. Queensland, Brisbane.]

Rectal temperature, pulse rate, respiratory rate, evaporative heat loss, skin temperature and behaviour of 2 Illawarra Shorthorn and 2 Zebu × Hereford calves were studied at 1 to 3, 6 to 8 and 12 to 13 months of age. At each age the calves were exposed for 7 hr. to temperatures from 86° to 108° F. and humidities of 6.5 to 16.6 g. moisture per c. ft.

Above 95° F. rectal temperature rose more and took longer to reach equilibrium in Shorthorns than in Zebu crosses. At the temperatures studied increased humidity caused greater stress than increased temperature. Pulse rate was not changed by temperature or humidity but in all atmospheric conditions and in both breeds the rate was lower in the older calves. The rate of panting was also lower in older calves in any combination of temperature and humidity. Evaporative heat loss increased with rising temperature, but increased humidity depressed this tendency. The evaporative loss increased regularly from 1 to 12 months in the Zebu × Herefords, but in the Shorthorns at 1 to 3 months it was negligible, and though it increased from 6 to 12 months of age it never attained the same level as in the crossbred calves. At 96° F. the Zebu × Herefords began to sweat, and skin temperatures fell. The results are compared with published data for Jersey calves. It was thought that the greater heat tolerance of Zebu cattle is at least partly due to better sweating mechanism and lower heat production.

CARTWRIGHT, T. C. **Responses of beef cattle to high ambient temperatures.** *J. Animal Sci.*, 1955, **14**, 350-362. [Texas Agric. Exp. Stat., Bluebonnet Farm, McGregor.]

Physiological reactions of Brahman, Hereford and F₁ Brahman × Herefords were recorded when they were kept for 8 hr. at 105° F. and relative humidity 50 per cent. in a heat chamber, and on summer pasture without shade. Respiration and pulse rate and rectal temperature were taken every

N.A. and R., October 1955

hour in the heat chamber, and in the field respiration rate was counted hourly and weight gain during the summer was recorded. A total of 366 sets of observations were made; animals tested in the field were tested also at least twice in the heat chamber.

In the heat chamber respiration rates and rectal temperatures rose; the increase was greatest in the Herefords, and the crossbreeds were intermediate, but nearer the Brahmans. A similar increase of respiration rate was found in the hot climate of the summer pasture. Brahman \times Herefords gained most weight, followed by Brahmans and then Herefords. Only summer gain was sufficiently heritable to be used in selection for heat tolerance.—T. D. Bell.

BRODY, S., RAGSDALE, A. C., THOMPSON, H. J. and WORSTELL, D. M. **Environmental physiology and shelter engineering with special reference to domestic animals.** 28. The thermal effects of radiation intensity (light) on milk production, feed and water consumption, and body weight in Holstein, Jersey and Brahman cows at air temperatures 45°, 70° and 80° F.

STEWART, R. E. and BRODY, S. 29. Effect of radiation intensity on hair and skin temperatures and on respiration rates of Holstein, Jersey, and Brahman cattle at air temperatures 45°, 70° and 80° F.

DALE, H. E. and BRODY, S. 30. Thermal stress and acid-base balance in dairy cattle. *Missouri Agric. Exp. Stat. Res. Bull.* No. 556, July 1954, pp. 20; No. 561, September 1954, pp. 36; No. 562, September 1954, pp. 27. [Columbia, Mo.]

For previous parts see Abst. 2498, Vol. 24.

28. Lactating Holstein and Jersey and dry Brahman cows were exposed for periods of 7 days to radiation intensities of 5, 40, 90, 130 and 180 B.t.u. per c. ft. per hr., supplied by combinations of incandescent and fluorescent lamps. Sometimes the radiation was continuous throughout the period, and sometimes varied to simulate natural daily changes. At each radiation intensity 3 temperatures, 45°, 70° and 80° F., were allowed. The effects on milk production, feed and water intakes and bodyweight were studied. At 45° an increase in radiation intensity did not affect any of these characteristics. The lactating cows were affected at the higher temperatures. Milk yield declined at 70° F. and still more at 80° F. The decline was even greater at higher intensities of radiation, but decline was less in Jerseys than in Holsteins. Butterfat percentage showed a slight increase related to the decrease in milk yield. The consumption of total digestible nutrients declined in these 2 breeds parallel to the fall in milk yield.

Vol. 25, No. 4

Water intake increased slightly in all breeds with increasing temperature and radiation intensity, and Jerseys and Holsteins lost weight slightly. Greater heat tolerance was aided by large surface area per unit bodyweight, by light, glossy, short hair and lower heat production. Greater age, advanced gestation and lactation and greater size tended to reduce heat tolerance.

29. Hair and skin temperatures and respiration rate of the cows were also studied. The absorption of radiation by the coat was first measured. It was least in the Brahmans and greatest in the Holsteins. As air temperature increased absorption decreased. Hair and skin temperatures increased with increasing radiation, and were highest in the Holsteins, which showed distinct signs of discomfort at the higher radiation intensities. Brahmans were least affected. Respiration rate was unaffected by radiation intensity, and in the Holsteins there was no difference between the predominantly black and the predominantly white animals. The complicated interactions of hair colour and structure and surface area are discussed.

30. The same cows were used, and in addition some were exposed to higher environmental temperature and greater radiation intensity for a short period, and some were starved for 5 days. The CO₂-combining capacity of plasma, CO₂ content of plasma and "arterialised" plasma, pH of blood, and ketone bodies in blood and urine were estimated. CO₂ capacity decreased with increasing thermal stress, and the decrease was greater in large lactating animals than in small non-lactating. The difference between breeds diminished at higher radiation intensities. At the same time there was a rise in pH of the blood, the condition being described as respiratory alkalosis. During the longer periods of exposure there was a tendency for the change in pH to correct itself: this did not appear in the short intensive periods of heat stress. Plasma was "arterialised" by saturation with normal human alveolar air. Plasma of blood taken under thermal stress lost CO₂ during arterialisation, because the CO₂ in the venous plasma had been reduced by panting. The analysis for CO₂-combining capacity was complicated by the effect of laboratory temperature: at high temperatures there was a loss of CO₂ from plasma during saturation. Ketone bodies in blood and urine were not affected by heat stress, even in the animals in which feed intake was slightly reduced, but during starvation for 5 days they increased and total organic acids in the urine decreased.

HART, J. S. and HEROUX, O. Exercise and temperature regulation in lemmings and rabbits. *Canad. J. Biochem. Physiol.*, 1955, **33**, 428-435. [Div. Appl. Biol., Nat. Res. Labs., Ottawa.]

Lemmings (*Dicrostonyx groenlandicus groenlandicus*) and rabbits were fed on mixed grain, fresh vegetables and water and were acclimatised for several weeks at $20 \pm 1^\circ \text{C}$. Oxygen consumption and colonic temperature were then studied during rest and work on a treadmill at different environmental temperatures. The index of body insulation was calculated from the ratio

Body temperature — Air temperature

Oxygen consumption

Of 16 lemmings, 8 died, apparently of heat stroke. In both species the increases in oxygen consumption during work were independent of and additive to those accompanying falls in environmental temperature. Work produced higher body temperatures in a warm environment and lower body temperatures in cold; the cross-over occurred in lemmings at -4°C . and in rabbits at -20°C . The insulation index in both species increased with falling environmental temperature and fell with work.—D. Duncan.

HILLERMAN, J. P. and WILSON, W. O. Acclimation of adult chickens to environmental tem-

perature changes. *Amer. J. Physiol.*, 1955, **180**, 591-595. [Dept. Poultry Husb., Univ. California, Davis.]

Light and heavy breeds of domestic fowl and Jungle Fowl were used to study the effects of sudden changes from high to low temperature and vice versa, and acclimatisation to high or low temperature, 95° and 60°F . Comparisons between breeds and between layers and non-layers were made.

Body temperature regulation was most highly developed in the Jungle Fowl and least in the heavy domestic breeds. The birds all became acclimatised in body temperature after 3 to 5 days at high or low temperature, and this acclimatisation was important in modifying the effects of environmental temperature. Water consumption was also important in heat tolerance. Respiration rate took longer, 8 to 10 days, than temperature to settle after a change in environmental temperature. Layers had higher body temperatures and respiration rates and consumed more water than non-layers at high temperatures. The respiration of Jungle Fowl was slower than that of domestic breeds.—T. D. Bell.

FRYER, J. H., MOORE, N. S., WILLIAMS, H. H. and YOUNG, C. M. A study of the interrelationship of the energy-yielding nutrients, blood glucose levels, and subjective appetite in man. *J. Lab. Clin. Med.*, 1955, **45**, 684-696. [Sch. Nutrit., Coll. Agric., Cornell Univ., Ithaca, N.Y.]

Twelve overweight men were given for 9 weeks diets supplying 1800 Cal. daily per head. In the three 3-week phases of the experiment the diets were, successively, low-carbohydrate, low-fat and low- or moderate-protein. At the end of each

phase samples of capillary and venous blood were taken before breakfast and at intervals during the day. Sampling times bore the same relation to meal times throughout. Satiety value of diets was assessed from records kept by the subjects. No correlation was found between the satiety values of the diets and capillary or venous levels of glucose or the difference between them.

In another group of 12 overweight men given a diet with 3000 Cal. for 1 week, fasting levels of glucose in capillary blood were of the same order as in the first group, but the rise of capillary blood glucose after both breakfast and lunch was more prolonged in those with the higher energy intakes.

FABRYKANT, M. (with ALLEN, J. F.) Clinical versus laboratory hypoglycemia. An analysis of 81 oral glucose tolerance tests with arterial and venous blood glucose measurements.

N.A. and R., October 1955

Metabolism, 1955, 4, 153-159. [Dept. Med., Post-Grad. Med. Sch., Univ. New York.]

Oral glucose tolerance tests with 100 g. glucose were made in 76 patients; venous and capillary blood samples were used.

In nearly all tests when the lowest blood sugar level fell below 60 mg. per 100 ml., clinical symptoms of hypoglycaemia occurred, but 7 patients showed no clinical disturbance when the arterial blood sugar was 44 to 62 mg. per 100 ml. In the other subjects the commonest symptoms were weakness and hunger, and their onset usually occurred before the lowest blood sugar levels, at values from 40 to 135 mg. per 100 ml. in capillary and 39 to 135 mg. in venous blood. The occurrence of symptoms in the tests was not related to their spontaneous occurrence, an indication of the diagnostic limitations of the test. There was no uniform behaviour of the arteriovenous glucose difference except that it was usually eliminated or even reversed at the lowest blood sugar levels.

5193

HOWARD, J. M. Studies of the absorption and metabolism of glucose following injury. The systemic response to injury. *Ann. Surg.*, 1955, 141, 321-326. [Army Med. Serv. Grad. Sch., U.S. Army.]

The subjects for oral glucose tolerance tests were 4 casualties with minor soft tissue wounds, 10 with major injuries and 6 healthy soldiers, all between 18 and 30 years old. The casualties were studied in the week after they were injured. The numbers in the same 3 categories given insulin tolerance tests were 4, 6 and 3.

Mean values for the 3 groups still in the same order were: fasting blood sugar 95, 119, and 85 mg. per 100 ml., peak blood sugar 165, 202 and 134 mg. per 100 ml., reached 45, 60 and 30 min. after intake of glucose and declining after 240 min. to 109, 130 and 84 mg. After injection of 0.1 unit crystalline insulin per kg. bodyweight the fasting blood sugar of 94, 113 and 83 mg. per 100 ml. fell to 56, 78 and 40 mg. after 30 min. Only in the severely injured group was the fasting level not regained within 120 min. The most pronounced impairment of glucose tolerance was in a burned patient on the day of injury, but by the fourth day after injury nearly normal tolerance had been regained.

The mechanism of the effect is not known.

FOURNIER, P. Relation entre l'utilisation des glucides de structure et l'ossification. [Relation between utilisation of structural sugars and ossification.] *C.R. Acad. Sci.*, 1955, 240, 1364-1366.

The method was that described in Abst. 745, Vol. 25. The diets of young rats contained, per cent., at the expense of starch, lyxose 3.5, mannose 10, galactose 4, lactose 7.6, melibiose 7.6 or raffinose 11.2; the last 4 provided the same proportion of galactose. Controls received starch as the only carbohydrate.

All the sugars except galactose gave much better retention of Ca than starch alone. Lactose, melibiose and raffinose were similar in effect, though the galactose they contain is in different forms.

It is suggested that all sugars which are not "energetic" may be "structural" (see Abst. 2213, Vol. 25). The extreme diversity of structure of sugars so far shown to affect calcification suggests that they have a simple action, otherwise many different transpositions and inversions of radicals would be involved. Unlike energy-giving carbohydrates, the structural ones may be metabolised through two-carbon steps. The hypothesis is expressed that they may be precursors of glycine. Ossein contains 25 per cent. of this amino-acid; most other animal proteins contain about 1 per cent. Reversible reactions between glycine and lactose might explain both the effects of lactose on calcium metabolism and the resorption of bone tissue in lactating females when lactose is being formed.—D. Duncan.

5196

LODDING, C. Galactosemia. *Acta paediat.*, 1954, 43, 569-574. [Univ. Paediat. Clin., Rikshosp., Oslo.] French, German and Spanish summaries.

Galactose tolerance curves are presented from an infant with galactosaemia, an infant with atresia of the bile ducts, an infant with signs of liver damage and a child with severe liver damage. Only in the first and the last were the curves abnormal. It is suggested that galactosaemia is not a secondary sign of congenital liver disease, but an independent primary disease.

CARLETON, F. J., MISLER, S. and ROBERTS, H. R. Comparison of the metabolism of C¹⁴-labeled lactose, glucose, and galactose in rats. *J. Biol. Chem.*, 1955, 214, 427-440. [Nat. Dairy Res. Labs., Inc., Oakdale, N.Y.]

Forty rats weighing from 180 to 200 g. were maintained on a sugar-free diet containing, per cent., casein 24, salt mixture 4, butterfat 6, cod liver oil 2, liver concentrate 2 and maize starch 62, with vitamins E, K and those of the B complex. Sixteen of the rats were given by intravenous injection 4 to 6 mg. D-glucose-U- ^{14}C (i.e., labelled in all C atoms), D-glucose-1- ^{14}C , D-galactose-1- ^{14}C or D-lactose-1- ^{14}C , and the rest received similar quantities by stomach tube, with or without 100 to 250 mg. carrier sugar, after being starved for 18 hr. Expired CO_2 , urine and faeces were collected and at the end carcasses were examined for distribution of ^{14}C .

Oxidation of glucose and galactose given by vein was rapid and 64 per cent. of the radio-activity of glucose was recovered as $^{14}\text{CO}_2$ in a few hours, with another 16 per cent. within 4 days. The yields of $^{14}\text{CO}_2$ from glucose-U- ^{14}C were slightly greater than those from glucose-1- ^{14}C . With galactose 61 per cent. of the activity was recovered as $^{14}\text{CO}_2$ in 24 hr., and with lactose only 7 per cent. in 48 hr. This suggests the presence of some lactase activity outside the digestive tract. The percentages of radio-activity recovered in the urine were from galactose 10, from glucose 5 and from lactose 83. The urine after lactose contained much unchanged lactose and 3 unidentified labelled components. Recoveries from faeces were so small as to suggest that they came from contamination with urine. The carcasses contained from 7 to 21 per cent. of the activity from glucose, 8 per cent. from galactose and 10 per cent. from lactose.

When the sugars were given by mouth glucose-U- ^{14}C was broken down to CO_2 to a greater extent than the other sugars. With lactose most of the $^{14}\text{CO}_2$ appeared in the first few hours and the metabolic picture was almost identical with that of glucose-1- ^{14}C , suggesting that most of the lactose was hydrolysed in the intestine. Glucose and galactose given together were better utilised than either sugar alone, but the respiratory ^{14}C was less. The peak of $^{14}\text{CO}_2$ activity was reached within 2 hr. with glucose, galactose or both, 2 to 4 hr. later with lactose. About 4-5 per cent. of the lactose activity was recovered in the faeces, partly as lactose and partly as unidentified substances. Recoveries from the carcasses were 35 to 42 per cent. after lactose or glucose, only 17 to 21 per cent. after the mixture of glucose and galactose.

SCHREIER, K. Über den Einfluss von Monosacchariden auf das Wachstum junger Ratten. [Effect of monosaccharides on the growth of young rats.] *Klin. Wochenschr.*, 1955, **33**, 188. [Dept. Exp. Radiol., Univ. Rochester, N.Y.]

Three groups of young rats of initial weight about 50 g. were given purified diets containing 56 per cent. glucose, fructose or galactose, and weight changes and urine output were measured for 10 days. Those having galactose showed no increase of weight and excreted very large volumes of urine. The other 2 groups gained weight normally and the urine volume was small. The polyuria of galactose-fed rats was associated with excretion of large amounts of amino-acids. More amino-acids were excreted by the groups having glucose or fructose than by comparable rats given starch as carbohydrate.—A. M. Copping.

PERKOFF, G. T. and ROSECAN, M. Relationship of dietary carbohydrate and fat to ketonuria in diabetic and nondiabetic subjects. *Metabolism*, 1955, **4**, 214-226. [Nat. Inst. Arthritis Metabol. Dis., Nat. Inst. Health, Bethesda, Md.]

The effect on ketone excretion of a change from customary diet to isocaloric diets high in fat and low in carbohydrate and then low in fat and high in carbohydrate was studied in 6 diabetic and 3 nondiabetic subjects. Ketone excretion was within normal limits in all subjects given their customary diets. Change to high-fat, low-carbohydrate diets caused small increases in ketone excretion in 3 well regulated diabetics and large increases in the other diabetics and in one nondiabetic. Change to low-fat, high-carbohydrate diets induced sharp reductions in ketonuria in 5 diabetic and 2 non-diabetic subjects. The disappearance rate of intravenously administered β -hydroxybutyric acid was studied in 2 diabetic subjects during high-fat and high-carbohydrate diet periods. The results suggested that changes in ketonuria were due to changes in rate of ketone production rather than in utilisation.

FALK, W. Beiträge zum Fruktose-Stoffwechsel bei Kindern. [Fructose metabolism in children.] *Ann. paediat.*, 1955, **184**, 319-351. [Kinderklin., Univ. Graz.] English and French summaries.

Tolerance tests with intravenous loads of fructose were made in 14 infants, 25 toddlers and 42

children of school age. In 20 healthy children there was a slight initial depression of blood glucose after the injection; the fructose disappeared within 2 hr. and there was no hypoglycaemic reaction. In the 5 children studied for this there was no fructose or glucose in the urine. In 7 healthy infants the fructose peak was higher than that of older children and clearance was slightly slower.

In 19 diabetic children given no insulin for at least 12 hr. before the test there was no important difference in fructose tolerance, though 8 of them had prolonged clearance times. Sometimes the blood glucose was considerably reduced. Three children with diabetic coma tolerated fructose well and in 2 there were falls in blood glucose and total reducing sugar.

Obese children had reduced fructose tolerance, and so had 5 out of 7 children with hepatitis, but in children with coeliac disease fructose metabolism was not impaired. In 7 infants with eczema fructose tolerance was high.

In double fructose tolerance tests on 5 healthy children the second fructose peak was only slightly higher than the first, but the total sugar peak was higher because of a rise in blood glucose. In 4 infants with coeliac disease this Staub effect was missing. Deoxycorticosterone reduced the tolerance for fructose and increased the drop in glucose level after the injection of fructose. Cocarboxylase did not affect the fructose curve, but increased the drop in glucose.

In healthy children there was a rise in blood pyruvic acid after fructose, but this was not seen in diabetics and was not affected by cocarboxylase. D. Duncan.

JARRETT, I. G. and POTTER, B. J. **The effect of glucose on blood pyruvate in sheep.** *Austral. J. Exp. Biol. Med. Sci.*, 1954, **32**, 757-762. [Div. Biochem. Gen. Nutrit., C.S.I.R.O., Univ. Adelaide.]

Five adult ewes were fed on wheat hay and lucerne chaff and fasted overnight before each experiment. A polythene tube was inserted into the jugular vein and filled with heparin in saline so that blood samples could be obtained without disturbing the sheep. After an initial sample was taken, 100 ml. solution containing 1 g. glucose per kg. bodyweight was injected during 5 min. Blood samples were taken 30, 60 and 90 min. later for estimation of pyruvate. Similar experiments were made on 7 lambs aged 3 to 4 weeks and removed from their dams 2 to 3 hr. before receiving glucose at the same rate, and on 4 rabbits. Control experiments were either with saline replacing glucose or with sheep anaesthetised with Nembutal.

In rabbits the mean initial blood pyruvate level was 1.36 mg. per 100 ml., and after glucose the

level rose at 30 min. to 0.78 mg. above that attained after saline. The normal level was regained within 90 min. In young lambs the increase after glucose was less, but still significant; pyruvate was highest at 30 min. and usually below the initial level at 90 min. In adult sheep the pyruvate rose steadily after glucose and was still high after 90 min. In adult sheep there was no effect of anaesthesia, but in lambs the pyruvate fell after either glucose or saline in anaesthesia.

ALBANESE, A. A., ORTO, L., ROSSY, J., DiLALLO, R. and BELMONT, A. **Effect of carbohydrates on blood amino nitrogen.** *Metabolism*, 1955, **4**, 160-165. [Nutrit. Res. Lab., St. Luke's Hosp., New York.]

Fructose given to human subjects after a 12-hr. fast at 1 g. per kg. bodyweight produced after 1 hr. about the same increase in blood amino-N as 0.3 g. protein per kg. bodyweight. Sucrose produced a smaller increase and glucose and a maltose-dextrin product had no significant effect. The increase of amino-N was inversely related to the total blood sugar. A protein-sparing activity of fructose is suggested, possibly due to readier production from glucose than from fructose of carbon structures which can be converted to amino-acids by transamination.—A. Hepburn.

GEIGER, E. and PINSKY, J. J. **Utilization and nitrogen-sparing effect of fructose in alloxan diabetic rats.** *Metabolism*, 1955, **4**, 166-173. [Dept. Pharmacol., Univ. S. California Med. Sch., Los Angeles.]

Synthetic diets were used. For one group of rats the diet was free from protein and the utilisation of fructose, glucose and sucrose was compared. In another group under better conditions protein at the rate of 1 g. daily per rat and a vitamin and mineral supplement were given and utilisation of the same sugars and of a mixture of glucose and fructose was studied. Fructose, sucrose and the mixture were utilised better than glucose and the difference in favour of fructose persisted for up to 25 days. The effect of giving protein separately from the sugars was examined in normal and diabetic rats. In normal animals fructose, like glucose, had a greater N-sparing effect when given with the protein than when sugar and protein were separated by 5 hr. In the diabetic rats the N-sparing effect of glucose disappeared or was much reduced, but that of fructose was maintained.

PATTERSON, J. W. **Effect of blood supply on the development of cataracts.** *Amer. J. Physiol.*

1955, 180, 495-497. [Dept. Anat., Sch. Med., W. Res. Univ., Cleveland, Ohio.]

In 25 rats on a diet containing galactose, the first cataract was slightly more often in the left eye. In 16 rats weighing from 75 to 145 g. the common carotid was ligated and cut, in 8 on the right side and 8 on the left. Sixteen other rats had sham operations. A week after operation all the rats were given a chow diet with 35 per cent. galactose added. When one carotid was cut, cataract appeared first in the opposite eye in 14 out of 16 rats, but after the sham operation it appeared in either eye.

In 36 rats made diabetic with alloxan or dehydroascorbic acid, cataracts first appeared in either eye or both with similar frequency. In 15 rats with a ligated carotid artery, given alloxan a week after operation, there was no preferential development of cataract on the unoperated side.

In 7 rats kept on normal diet for 40 days after carotid ligation and then given the galactose diet, all the cataracts appeared in the contralateral eyes.

It is concluded that galactose produces cataract by local action on the eye and that a good blood supply therefore favours galactose cataract, and that diabetic cataract does not result from local action of glucose on the eye, but possibly from lack of insulin.—D. Duncan.

SCHULMAN, J. L. and SATUREN, P. **Glycogen storage disease of the liver. 1. Clinical studies during the early neonatal period.**

CORI, G. T. and SCHULMAN, J. L. **2. Enzymic studies.** *Pediatrics*, 1954, 14, 632-645; 646-650. [Dept. Paediat., Jewish Hosp., Brooklyn, N.Y.] Spanish summary.

1. Glycogen storage disease is described in 3 infants in the first few days of life. The results of estimations of liver glycogen and glucose-6-phosphatase and of glucagon tolerance tests are reported for 2 of the infants. Electroencephalograms were normal while blood sugar was low.

2. Glucose-6-phosphatase and phosphoglucomutase were estimated in livers of 6 infants, 2 of them with von Gierke's disease (glycogen storage disease) and in the liver of a 4-months foetus. Cell counts were made in 6 of the 7 livers. In livers of

infants with glycogen storage disease glucose-6-phosphatase activity was low and phosphoglucomutase activity normal compared with controls, whether activity was based on tissue weight or cell count. In the foetal liver, cell count was high and both enzyme activities, expressed on a cell count basis, were low; on a tissue weight basis, glucose-6-phosphatase activity was 9 times that of liver in von Gierke's disease and phosphoglucomutase activity was within the normal range for infant liver.—F. C. Aitken.

TODD, C. M. **The antiketogenic action of sorbitol in rats.** *Austral. J. Exp. Biol. Med. Sci.*, 1954, 32, 827-833. [Dept. Biochem., Med. Sch., Univ. Otago.]

Rats fed on stock diet were anaesthetised with sodium amytal. Some were previously made diabetic with alloxan and maintained with insulin until they were required for experiment, when ketosis was induced in some by withdrawal of the insulin. In other rats ketosis was produced with phloridzin. Blood samples were taken for estimation of acetone bodies, reducing sugar and fructose.

In ketosis produced by phloridzin, 0.18 g. sorbitol, but not mannitol, given by vein increased the blood sugar and reduced the concentration of ketone bodies. In starved diabetic rats with low ketone body levels, sorbitol and fructose reduced them further. A similar effect was obtained in fat rats which had 8 to 15 mg. acetone per 100 ml. after 48 hr. without food. Glycerol also reduced the blood ketone level, but duleitol did not.

Pronounced ketosis was produced in diabetic rats given excess butter for a week, and in these rats the blood ketones were only slightly and briefly reduced by sorbitol or fructose. In alloxan-diabetic rats severely ketotic and semi-comatose after withdrawal of insulin there was some drop in ketones, but not in fructose, after injection of sorbitol.

Sorbitol might be used as an adjunct to insulin in human diabetic ketosis.—D. Duncan.

DINKHAUSER, G. Studio sulle variazioni dell'N amino del sangue dopo ingestione di proteine in bambini in condizioni normali e patologiche. [Variations in amino-N in the blood after ingestion of protein in children in normal and pathological conditions.] *Arch. ital. Pediat. Puericolt.*, 1955, 17, 91-124. [Clin. Paediat., Univ. Rome.] French, English and German summaries.
- A test meal of caseinate sweetened with saccharine was given to infants and children fasted for 8 or 9 hr. Blood amino-acids were estimated before and $\frac{1}{2}$, 1, 2, 3, 4 and 5 hr. after the meal. After preliminary trials with different preparations Plasmon, a sodium caseinate with 76 per cent. casein, was selected.
- In 8 normal children the blood amino-N was highest $1\frac{1}{2}$ hr. after the meal, and reached fasting level usually in about 5 hr. In 3 infants and a 7-year-old child the peak value was between 3.38 and 3.78 mg. per cent. after a meal of 1.32 g. casein per kg. Two children showed secondary peaks in blood amino-N, 3 and 4 hr. after the meal, respectively. The peak values, between 2.9 and 3.8 mg. per cent., are taken as characteristic for normal children.
- In 5 dystrophic children the peaks were low, from 1.99 to 2.89 mg. per cent., and in 1 the peak was not reached until 2 hr. after the meal. In a sixth child, with starch dystrophy, the peak value was 3.39 mg. and the curve declined very rapidly. In an infant with hepatic insufficiency the peak value was 3.85 mg., but by the end of the second hour the level was little above the fasting value, and there was another slight rise after 5 hr. Five infants with alimentary intoxication and acetonaemia had very irregular responses, showing the important effects of dehydration. Two infants with cystic fibrosis of the pancreas showed small peaks, slowly attained. It is suggested that a secondary peak in one of these infants was attributable to protein breakdown by the intestinal flora.—D. Duncan.

- Balances of N, Na and K were measured in 2 groups each of 4 patients who had undergone cholecystectomy or sub-total gastrectomy and who were given glucose, alcohol, protein hydrolysate and KCl by vein. The average intakes for the periods 1 to 5 and 1 to 8 days after operation for the respective groups are tabulated; the greatest amounts given were 53.3 Cal., 0.49 g. N and 2.5 m. equiv. K per kg. bodyweight in 24 hr. The change in lean tissue (g. N balance \times 30) is shown graphically for each patient.
- The results, regarded as only preliminary, appear to indicate that the loss of lean tissue after operations can be diminished by giving intravenously large amounts of these nutrients.

MITCHELL, H. H. **The dependence of the biological value of food proteins upon their content of essential amino acids.** *Wiss. Abh. Deutsch. Akad. Landwirtsch. Berlin*, 1954, **5**, 279–325. [Div. Animal Nutrit., Univ. Illinois, Urbana.] German summary.

A critical review, with 262 references. It includes tables, based mostly on published results, which give for some 30 animal and vegetable proteins the amino-acid composition compared with that of whole egg, the limiting amino-acid, the chemical score and essential amino-acid index as computed by the author, and the biological value by the author's method and the protein efficiency ratio for the growing rat, with some values for the pig and the dog. There are also 5 graphs showing the correlations between the results of different methods of chemical and biological evaluation. From these it is concluded that the essential amino-acid index is a satisfactory means, better than the chemical score, of predicting from chemical data the biological value of a protein or a mixture of proteins for the growing rat and, so far as data go, for the growing pig and dog. Whether this applies also to children is not yet certain. Next, supplementation of proteins is discussed. Damage of proteins by heating is

briefly referred to, with a warning that prediction of biological value from chemical data may then be hazardous. The special needs of growing poultry are reviewed, with a table of essential amino-acid requirements for the chicken and the turkey poult in comparison with those for the growing rat and pig and the child. Here prediction of biological value is difficult for want of a satisfactory reference protein. A section on the requirements of mature animals, including man, has a table comparing the biological values of several proteins for the growing rat with those for the adult rat, dog and man. The high correlation between the values for adult man and the growing rat ($r = +0.915$) suggests that the biological value of proteins for adult man may be satisfactorily predicted from the essential amino-acid indices. In conclusion, the special case of the ruminant is discussed. Here chemical data are no guide to biological value, because of the intervention of the micro-organisms in the rumen.

FORBES, R. M. and YOHE, M. **Net protein value of blood fibrin for the albino rat: evaluation of nitrogen balance and carcass analysis methods.** *J. Nutrition*, 1955, **55**, 493–498. [Div. Animal Nutrit., Univ. Illinois, Urbana.]

Ten rats were each given 6 g. daily of a diet containing 10 per cent. protein as commercial blood fibrin for 2 weeks, then for 2 weeks a standardising diet with 4 per cent. whole egg protein; N balances were estimated during the last 7 days of each period and the biological value, true digestibility and net protein value were estimated. Thirty weanling male rats were used for estimation of net protein value from carcass analysis; for 7 days 10 received 28 per cent. protein in stock diet, 10 received 10 per cent. whole egg protein and 10 received 4 per cent. whole egg protein. Food intake was again 6 g. daily. Five rats from each group were then given the diet with 10 per cent. blood fibrin protein while the other 5 received an N-free diet. After 10 days all were killed and the carcasses were analysed for total N and water. Bender and Miller (Title 2726, Vol. 23) proposed that a predetermined ratio of N to water in the carcasses be used in order to eliminate the necessity of estimating carcass N. The reliability of this technique was investigated in this study.

The ratio 100 N : H₂O was 4.81, S.D. ± 0.114 . The standard error in estimating N content from water content was 0.08 per cent., and since this would cause an error of 20 per cent. in estimation of net protein content under the conditions of the experiment, it is considered safer to estimate N directly.

The net protein value of the blood fibrin, per cent., was 76.6 ± 1.57 and 77.2 ± 1.83 by the 2

N.A. and R., October 1955

direct methods and 80.8 ± 2.88 by calculation from water content.—G. F. Garton.

5223

FORBES, R. M. and YOHE, M. **Effect of energy intake on the biological value of protein fed to rats.** *J. Nutrition*, 1955, **55**, 499-506. [Div. Animal Nutrit., Univ. Illinois, Urbana.]

Six groups of 5 weanling rats were given 4, 6 or 8 g. daily for 3 periods of 14 days, of diets containing 4 per cent. minerals, 2 per cent. fibre and 10 per cent. ether extract with 10 per cent. protein supplied by soya bean meal, whole egg or blood fibrin plus methionine; 3 of the groups received the proteins in the above order, for the other 3 the order was reversed. The 2 test diets contained 1.6 per cent. N, the whole egg protein diet 0.67 per cent. Biological values were estimated by the N balance method; the last 7 days of each test were the collection period.

At food intake of 4 g. the biological values of the soya bean protein and the methionine-supplemented fibrin were 59.1 and 74.3. At 6 and 8 g. intake the values did not differ significantly with intake and the averages were 71.0 and 96.8.

BEHM, G. **Über den Einfluss der Futtermenge auf die Menge des Darmverlust-Stickstoffs. [The effect of food intake on the amount of faecal nitrogen.]** *Arch. Tierernährung*, 1955, **5**, 52-60. [Inst. Tierernährung, Humboldt Univ., Berlin.]

The N-free diet contained, per cent., sugar 8, olive oil 7, minerals 4, potato starch 80 and filter paper 1. When it was given to appetite for 6 days 6 rats weighing from 61 to 69 g. ate on the average 8.78 g. dry food daily and excreted 14.5 mg. N in the faeces. When the same rats, now weighing 82 to 93 g., were restricted to about 4.68 g. daily the faecal N fell to 9.08 mg. In two more studies the rats weighed about 100 and 110 g. and were allowed 7.69 and 2.95 g. food, when they lost 16.74 and 7.72 mg. faecal N.

With 6 heavier rats, weighing in 4 successive experiments about 170, 185, 200 and 208 g., food intakes of 12.75, 9.38, 14.66 and 5.9 g. led to faecal N losses of 31.96, 21.49, 31.49 and 17.11 mg.

It is concluded that the food intake has an important influence on the output of endogenous faecal N, as suggested by Columbus (Abst. 3287, Vol. 25).—D. Duncan.

RIGGS, L. K., BEATY, A. and MALLON, B. **Nutritive value of whey powder protein.** *J. Agric. Food Chem.*, 1955, **3**, 333-337. [Nat. Dairy Res. Labs., Oakdale, N.Y.]

Vol. 25, No. 4

Spray-dried or roller-dried whey and lactalbumin were compared in rat growth experiments. The crude protein ($N \times 6.25$) of spray-dried whey was superior to that of roller-dried, with higher digestibility and nutritive value. Supplements of lysine partly corrected the deficiency of the latter. Lactalbumin promoted better growth and efficiency than either of the whey proteins. Protein concentrates prepared by heat coagulation of ethanol extracts of spray-dried whey powder were equal to lactalbumin, but those from roller-dried were inferior.—T. D. Bell.

5226

CAHN, A. J. **Commercial dried egg albumen as a protein source for the growing rat.** *Austral. J. Exp. Biol. Med. Sci.*, 1954, **32**, 819-825. [Dept. Biochem., Univ. Melbourne.]

Male weanling rats were fed for 15 to 16 weeks on diets containing as source of N 15 per cent. dried egg albumin, or 15 per cent. casein supplemented with methionine and cystine to levels comparable with egg albumin, or 7.5 per cent. of each.

There was no difference between groups in weight gain or food intake. About a third of the animals given egg albumin developed fatty infiltration of the liver, with high total fat and cholesterol concentrations. Signs of biotin deficiency, curable by biotin, developed in the animals given egg white, but the presence or absence of added biotin in the diet had no effect on the proportion of animals developing liver abnormalities; many of the animals on albumin developed mild diarrhoea.—C. Warner.

CALLOWAY, D. H., GROSSMAN, M. I., BOWMAN, J. and CALHOUN, W. K. The effect of previous level of protein feeding on wound healing and on metabolic response to injury. *Surgery*, 1955, **37**, 935-946. [Quartermaster Food and Container Inst. Armed Forces, Chicago, Ill.]

Groups of rats were given a stock diet and when bodyweight was between 250 and 300 g. were divided into 3 groups. For a standardisation period of 2 weeks they received 1, 2 or 3 times the minimum N requirement in the form of purified diet supplying 48 Cal. daily. At the end of that time balances of N were measured and some of the animals were killed. The remaining rats were subjected to surgical injury and to burns by water at 90°C. During recovery they were given the same purified diets and analyses of urine for N were made at 2-day intervals. At 4, 7 or 10 days after injury the rats were killed. Wounds were examined histologically and their tensile strength was measured; livers were analysed and weight of adrenals was recorded.

Variation in intake of N before injury was reflected only in N content of liver at the end of the standardisation period and in the amount of N excreted in urine on the day of injury and the day following it. During recovery the retention of N and the N content of the liver were greater with the high than with the low level of feeding.

It was concluded that for wound healing the maintenance of a high level of nutrition had no advantage over minimum adequate feeding.

SERENI, F., McNAMARA, H., SHIBUYA, M., KRETCHMER, N. and BARNETT, H. L. Concentration in plasma and rate of urinary excretion of amino-acids in premature infants. *Pediatrics*, 1955, **15**, 575-585. [Dept. Paediat., New York Hosp.—Cornell Med. Centre.] Spanish summary.

Clearances of total amino-acids, individual amino-acids and endogenous creatinine were measured in 4 groups of healthy fasting subjects, namely: 5 premature infants under 17 days; 7 premature infants between 28 and 51 days; 7 full-term infants between 9 days and 17 months; 4 children between 4 and 10 years and 5 adults between 21 and 40 years. Blood and urine were analysed. The results are tabulated for individuals, with means for the 4 groups.

The concentration of total amino-acids in the plasma was higher in the premature infants than in full-term infants, children or adults, owing mainly to higher concentrations of glycine, serine, threonine, glutamine, tyrosine and phenylalanine. The clearances and rates of excretion, relative to surface area, of total amino-acids and of most individual amino-acids were highest in the group of older premature infants. The results indicated that the high rate of excretion of total amino-acids compared with that of children or adults was due not to the higher concentration in plasma, but to a lower rate of re-absorption by the renal tubules. The younger premature infants, in addition, had a low rate of glomerular filtration, which caused their rate of excretion to resemble that of children and adults.—W. M. Deans.

CLEMETSON, C. A. B. and CHURCHMAN, J. Plasma amino-acid levels following protein ingestion by pregnant and non-pregnant subjects. *J. Obstet. Gynaecol. Brit. Empire*, 1955, **62**, 390-394. [University Coll. Hosp., London.]

Random samples of plasma from 5 men and 5 non-pregnant women contained similar amounts of amino-acids with mean values of 4.90 and 4.89 mg. per 100 ml.; the mean value for 10 pregnant women was 3.30. The values in 4 normal men, 4 pregnant women and 4 women *post partum* rose to a maximum about 3 hr. after ingestion of 100 g. calcium caseinate and slowly fell to the original level after 12 hr. Amino-acid curves obtained

from the pregnant women were similar to the others but did not reach such a high peak. One patient with severe pre-eclampsia had a delayed peak.

WALSHE, J. M. Disturbances of aminoacid metabolism following liver injury: a study by means of paper chromatography. *Quart. J. Med.*, 1953, **22**, 483-505. [Med. Unit, University Coll. Hosp. Med. Sch., London.]

Amino-acid patterns were examined in blood and urine from normal subjects and 119 patients with acute or chronic liver injury. Urine from patients with massive hepatic necrosis contained 30 different amino-acids. The large excretion of amino-acids usually heralded death. Changes in the plasma amino-acids were less striking. Urine amino-acids sometimes increased in severe acute hepatitis, but many were normal. An increase in cystine excretion was considered a sensitive index of impaired amino-acid metabolism.

A few patients with chronic hepatitis and cirrhosis of the liver had a high excretion, particularly of 2 or 3 amino-acids. Occasionally the increase disappeared, and this was associated with clinical remission. Patients with obstructive jaundice or focal lesions of the liver had normal amino-acid metabolism.—A. Hepburn.

WESTALL, R. G. The amino acids and other ampholytes of urine. 3. Unidentified substances excreted in normal human urine. *Biochem. J.*, 1955, **60**, 247-255. [Med. Unit, University Coll. Hosp. Med. Sch., London, W.C.1.]

Vol. 25, No. 4

For parts 1 and 2 see Abst. 1227, Vol. 23 and Title 744, Vol. 24.

Fractionation of 100 litres of urine from a normal adult on ion-exchange columns, followed by chemical and paper chromatographic techniques, allowed 27 common urinary constituents which reacted with ninhydrin to be identified. In addition to these, 38 unidentified substances which reacted with ninhydrin, 5 after hydrolysis, were found. Of these, 10 were stable to acid hydrolysis, the rest mostly yielding amino-acids.—A. Hepburn.

SUTTON, H. E. and CLARK, P. J. A biochemical study of Chinese and Caucasoids. *Amer. J. Phys. Anthropol.*, 1955, **13**, 53-65. [Inst. Human Biol., Univ. Michigan, Ann Arbor.]

The Chinese subjects were 10 men and 8 women living under western conditions in the United States for 2 years or more; the Caucasoids were 16 men and 13 women, mostly of western European origin. Analysis of urine showed that the Chinese excreted significantly more alanine, β -aminoisobutyric acid, histidine, leucine, lysine, tyrosine and uric acid. How far these differences are racial is not clear, but the fact that the Chinese group included several married couples of whom one excreted β -aminoisobutyric acid and the other did not suggests that the excretion of this substance does not depend on diet.—W. M. Deans.

SHREEVE, W. W., HUTCHIN, M. E., HARPER, H. A., MILLER, C. D. and DOOLAN, P. D. Excretion of amino acids in nephrosis. *Proc. Soc. Exp. Biol. Med.*, 1955, **88**, 510-514. [Metabol. Res. Facility, U.S. Naval Hosp., Oakland, Calif.]

A man with nephrosis associated with glomerulonephritis had far more than the normal amounts of amino-acids, notably the essential ones, in the urine. A woman with nephrosis had also aminoaciduria when fasting, but it was less severe. Both tended to have low amounts of several amino-acids in the blood. Infusion of an amino-acid mixture to raise the blood concentration and inulin clearance tests showed that the percentage of filtered amino-acids excreted in normal and nephrotic subjects was increased. Intravenous administration of adrenocorticotrophic hormone for 9 to 10 days produced a fall in excretion of amino-acids in one nephrotic subject, but had no definite effect on 2 normal subjects.

ALBANESE, A. A., HIGGONS, R. A., HYDE, G. M. and ORTO, L. Biochemical and nutritional effects of lysine-reinforced diets. *Amer. J. Clin. Nutr.*, 1955, **3**, 121-128. [Nutrit. Res. Lab., St. Luke's Hosp., New York.]

Fifteen infants aged from 1 to 27 months were studied for from 9 to 21 weeks to find the effects of lysine supplements on anthropometric and body-weight changes, N balance, Hb, total plasma protein and blood lysine. The lysine-supplemented diets were given for from 3 to 4 weeks, preceded and followed by control periods of equal duration during which the infants received standard mixtures of fresh or evaporated milk, the vitamin and mineral content of which was as high as, or higher than, the recommended levels. The supplements were given as L-lysine hydrochloride at the rate of 100 mg. per kg. bodyweight daily. Controls were 9 infants aged 2 to 18 months who received no lysine supplement.

The bodyweights and N balances of 5 of the 15 infants were much better with the lysine supplements. In 6 infants weight gains were not affected, but more N was retained when the lysine supplements were given. Blood protein also rose during supplementation. The other 4 infants showed no improvement when lysine was added to the diet, but their growth rate was already well above average, so the lysine supplements were effective only with children who were not getting adequate nourishment. It is concluded, therefore, that the nutritive value of many infant foods, including cow's milk, can be substantially improved by small supplements of lysine.

ROSE, W. C., LEACH, B. E., COON, M. J. and LAMBERT, G. F. **The amino acid requirements of man. 9. The phenylalanine requirement.** *J. Biol. Chem.*, 1955, **213**, 913-922. [Div. Biochem., Noyes Lab. Chem., Univ. Illinois, Urbana.]

This paper continues the detailed presentation of results discussed in Abst. 3891, Vol. 19, using the general technique described in Abst. 3803, Vol. 25.

Six men were kept in slightly positive N balance by 0.8 to 1.1 g. L-phenylalanine daily and consequently about 2.2 g. L-phenylalanine daily is suggested as a safe intake. In 3 subjects an amount of DL-phenylalanine equal to or slightly in excess of their minimum L-phenylalanine requirement could maintain positive N balance, but D-phenylalanine alone in amounts up to 2.2 g. daily gave strongly negative N balances, suggesting that up to about 0.5 g. D-phenylalanine daily, but no more, could be inverted.—C. Warner.

5244

LANGNEER, R. R. and VOLKMAN, C. M. **The fate of ingested acetyl-L- and D-tryptophan in the human subject.** *J. Biol. Chem.*, 1955, **213**, 433-437. [Dept. Biochem., Univ. Texas Dent. Branch, Houston.]

After ingestion of 2.46 g. acetyl-D-tryptophan, 3 adult subjects excreted 211 to 670 mg. in the urine and 1254 (incomplete) to 1811 mg. in the faeces. After ingestion of 2.46 g. of acetyl-L-tryptophan, one subject excreted 100 mg. in the urine and 166 mg. in the faeces. No free tryptophan was excreted.

It is suggested that the transport of acetyl-L-tryptophan across the intestinal mucosa is by enzyme action, not by simple diffusion.

C. Warner.

CASTRO, V. and MONACO, P. **Comportamento di alcuni aminoacidi liberi durante il decorso del digiuno. [Behaviour of some free amino-acids during fasting.]** *Arch. Fisiol.*, 1954, **54**, 170-183. [Ist. Fisiol., Univ. Palermo.] English summary.

Thirty-seven rats, weighing from 130 to 170 g., were maintained on a normal diet. Groups of 5 or 7 were killed after having fasted for 6, 12, 16, 39, 72, 96 or 120 hr., and 5 free amino-acids were estimated chromatographically in the liver, heart muscle and skeletal muscle.

In the liver the concentration of aspartic acid, glutamic acid and glycine fell slightly in the first 12 hr., and then rose, reaching the highest value after 39 hr. Alanine and threonine rose steeply, the highest value here also being after 39 hr. The values for all 5 then fell steeply to below the initial value, except that for glycine, which did not vary greatly with lapse of time. The value for threonine did not rise again. The values for alanine, glutamic acid and aspartic acid rose again after 96 hr. and had passed the initial values after 120 hr.

Aspartic acid and threonine could not be measured in heart and skeletal muscle. In skeletal muscle, alanine, glutamic acid and glycine rose at first, alanine beginning to fall after 39 hr., and glutamic acid and glycine after 72; they were still falling after 120 hr. In heart muscle the changes in concentration were less; glycine remained nearly constant, and glutamic acid and alanine began to fall after 39 hr., alanine having first risen somewhat; they were still falling slightly after 120 hr.—E. M. Hume.

the transformation in the organism of parenterally injected protein of serum, kidney and liver.] *Biokhimiya*, 1954, **19**, 414-421. [Inst. Khirurg., Akad. Med. Nauk SSSR, Moscow.]

Proteins of serum, liver and kidney containing labelled methionine were injected into rats and rabbits in an attempt to elucidate the process of incorporation into the tissues. Full experimental details are given, including preparation of labelled serum protein and liver and kidney homogenates and separation of liver cell nuclei. Both homologous and heterologous serum proteins injected parenterally were used in the formation of the protein of liver cell nucleus and cytoplasm in rats, without preliminary splitting. Injection of homologous and heterologous serum protein into both rats and rabbits led to increased radio-activity of the plasma fibrinogen, the relative specific activity of which was appreciably higher than that of the liver proteins. Intra-abdominal injection of proteins of serum and of liver and kidney homogenates was followed by their incorporation into tissue protein, as was injection directly into the bloodstream, without breakdown into amino-acids.

PORTMAN, O. W. and MANN, G. V. The disposition of taurine- S^{35} and taurocholate- S^{35} in the rat: dietary influences. *J. Biol. Chem.*, 1955, **213**, 733-743. [Dept. Nutrit., Harvard Sch. Pub. Health, Boston, Mass.]

Rats were fed for 45 to 60 days on diets varying in content of organic S, fat and cholesterol and then the bile duct was cannulated and taurine- S^{35} was given through the cannula into the duodenum. Animals fed on a stock diet excreted about 63 per cent. of the injected S^{35} in 24 hr., about 17 per cent. in the bile as taurine conjugated with bile acids, 45 per cent. in the urine as neutral S and 1 per cent. in the faeces. Animals fed on a diet low in organic S and high in cholesterol and fat excreted very little S^{35} in the urine, excretion in the bile being normal. Moderate reduction of the fat and cholesterol content of the diet allowed somewhat increased urinary excretion of S^{35} ; addition of methionine or high levels of casein gave normal urinary and reduced bile S^{35} excretion. An important cause of these differences appeared to be a low intrinsic taurine content of the bile when the diet was low in organic S. A considerable amount of S^{35} remained in the tissues, about half in the skeletal muscles. The animals fed on purified diets excreted much less total bile acid, particularly cholic acid, than did those on the stock diet.

When sodium taurocholate labelled with S^{35} was injected into the duodenum, most was absorbed from the intestine and excreted unchanged in the bile; only small amounts were excreted in the faeces or hydrolysed and excreted in the urine. No radio-activity was found in lymph from the thoracic duct. The findings are consistent with the classical hypothesis of Schiff, that there is an entero-hepatic circulation of conjugated bile acids.

WU, C. Effect of ethionine on the urinary nitrogenous constituents of adult rats. *Arch. Biochem. Biophys.*, 1955, 56, 230-234. [Sect. Biochem., Mayo Clin., Rochester, Minn.]

Groups of 5 rats of both sexes were fasted for 18 hr. before intraperitoneal injection of ethionine, methionine or other amino-acids. Some of the rats were spayed or castrated. Ethionine produced an increase in the urinary excretion of ammonia, urea, uric acid, creatinine and non-ethionine α -amino-N. The excretion of both ethionine and non-ethionine α -amino-N was increased by castration and reduced either by simultaneous injection of methionine or cysteine or by treatment with testosterone.—G. F. Garton.

ARMSTRONG, M. D. The phenylalanine and tyrosine requirements of the rat. *J. Biol. Chem.*, 1955, 213, 409-414. [Lab. Study Hereditary Metabol. Disorders, Coll. Med., Univ. Utah, Salt Lake City.]

After 2 days of depletion, rats were given diets containing an amino-acid mixture. The effect on growth of different amounts of phenylalanine in the absence of tyrosine and in the presence of excess (1 per cent.) tyrosine, and of different amounts of tyrosine in the presence of 0.6 per cent. phenylalanine was measured.

Requirements for optimum growth were 1.2 per cent. phenylalanine alone or 0.6 per cent. phenylalanine plus 0.3 to 0.4 per cent. tyrosine. It is suggested that the route of metabolism of phenylalanine is not directly through tyrosine, but to some derivative which can be either converted to tyrosine or metabolised further.—C. Warner.

5258

SAUBERLICH, H. E. and SALMON, W. D. Amino acid imbalance as related to tryptophan requirement of the rat. *J. Biol. Chem.*, 1955, 214, 463-473. [Dept. Animal Husband., Agric. Exp. Stat., Alabama Polytech. Inst., Auburn.]

Addition of gelatine or oxidised casein, both devoid of tryptophan, to a diet containing 7 to 10 per cent. casein and adequate nicotinic acid depressed growth. Digestion and absorption of protein appeared to be normal, but plasma tryptophan was low and urinary tryptophan high; addition of tryptophan to the diet abolished these effects.—C. Warner.

ROTHSTEIN, M. and MILLER, L. L. The metabolism of δ -aminovaleric acid- δ -C¹⁴. *Arch. Biochem. Biophys.*, 1955, 54, 1-5. [Dept. Radiation Biol., Sch. Med. Dent., Univ. Rochester, N.Y.]

δ -Aminovaleric acid- δ -¹⁴C, either alone or with a suspected metabolite, glutarate, formate or ornithine, was injected intraperitoneally into male rats. Urine was collected for 18 hr. and the radio-activity of suspected metabolites was estimated. In another experiment the aminovaleric acid was injected into 2 rats and the radio-activity of the respired CO₂ was measured; glutamic acid, aspartic acid and arginine were isolated from the proteins of the abdominal organs of these animals and tested for ¹⁴C activity.

The injected δ -aminovaleric acid was rapidly oxidised to CO₂; glutaric acid appeared to be an important product of its intermediary metabolism. No radio-activity was detected in formate or ornithine in the urine. It is suggested that glutaric acid may be a common metabolite of δ -aminovaleric acid and lysine.—G. A. Garton.

5262

JAFFÉ, W. G. and BUDOWSKI, P. Influencia de la dieta sobre la concentración del glutatión en ratones. [Effect of diet on the concentration

N.A. and R., October 1955

of glutathione in mice.] *Acta cientif. venezol.*, 1954, 5, 131-134. [Inst. Nac. Nutric.] English summary.

Three experimental diets were used; diet 1 consisted mainly of soya and maize, with 24 per cent. protein and reinforced with minerals and vitamins but deficient in vitamin B₁₂. The other diets were based on cooked black beans (*Phaseolus vulgaris*) and raw pigeon peas, respectively, and contained 10 per cent. crude protein deficient in methionine or methionine and tryptophan. All the mice received diet 1 to begin with. Different groups of from 3 to 10 mice received for a month before they were killed one of the above diets with or without supplements of vitamin B₁₂, methionine and tryptophan singly or together. At the end, blood and liver glutathione were estimated.

There was no significant effect of any diet on the concentration of glutathione in the red cells. The concentration in the liver was reduced when methionine was deficient; the lowest values were obtained on the diets low in methionine when these were supplemented with vitamin B₁₂. In mice deficient in vitamin B₁₂ there was no significant fall in liver glutathione except when they were starved for 24 hr. before death. Deficiency of tryptophan had no apparent effect.—D. Duncan.

RIDDELL, A. G., KOPPLE, P. N. and McDERMOTT, W. V. The etiology of "meat intoxication" in the Eck fistula dog. *Surgery*, 1954, 36, 675-684 (with discussion 684). [Dept. Surg., Harvard Med. Sch., Boston, Mass.]

Eleven of 19 dogs which underwent the operation survived and in them 20 attacks of "meat intoxication" were studied. It was found that signs appeared only when ammonia in blood was raised to a high level and sustained there for several hours. The increase was produced by giving meat or urea; ammonium salts were less effective because of the frequency of vomiting. Urease by vein also brought about attacks. The implications for human surgical treatment are discussed.

KIERSZ, J. Über den Einfluss von Nierengewebsentfernung und Diät auf den Harnstoffspiegel im Blut. [The effect of removal of kidney tissue and of diet on blood urea.] *Arch. inter. nat. Pharmacodyn.*, 1955, 101, 237-246. [Physiol. Inst., Med. Akad., Białystok, Poland.]

Ten young adult dogs weighing from 7.3 to 17.4 kg. were kept on stock diet and blood urea was estimated. In 5 dogs one kidney was removed and 10 days later also three-quarters of the other kidney. In the other 5 the operations were reversed. The dogs then received a carbohydrate diet with little fat, plant protein and minerals, and blood urea was studied for 3 weeks, after which they received a diet rich in protein.

There was no great difference between the 2 groups. The greatest change in blood urea was a sharp rise in the first few days after the second operation, when urine output was low; but the level reached was never very high. The mean difference from pre-operative blood urea values was only 22 mg. per cent. As urine output increased the blood urea declined to about 70 mg. per cent. When the high-protein diet was introduced the blood urea rose to an average of more than 280 mg. per cent. in 12 days, signs of toxicity developed and the dogs died, except 3 which were returned to the low-protein diet.

In dogs examined after death there was some hypertrophy of the remaining kidney cortical tissue.—D. Duncan.

FATS AND OTHER LIPIDS

5266

SNYDERMAN, S. E., MORALES, S. and HOLT, L. E. (Jr.) The absorption of short-chain fats by premature infants. *Arch. Dis. Childhood*, 1955, 30, 83-84. [Dept. Paediat., Coll. Med., Univ. New York.]

Six premature infants, 5 to 43 days old and between 1350 and 2010 g. in weight, were the subjects of fat balance studies for 4-day periods.

Tributyrin and triacetin were almost completely

absorbed when substituted for butterfat and were better than infant oil in this respect. The weight gains of the infants on tributyrin and triacetin mixtures were always better than those on butterfat, but somewhat less than those on maize oil mixtures because of the higher energy value of the latter.

It is suggested that the portal mechanism, by which the short-chain fats are absorbed, is unimpaired and that the lacteal mechanism alone

is affected. The substitution of the short-chain fats for butter appears to have little or no advantage for supplying energy, since shortening the fatty acid chain brings a corresponding loss in energy yield.—F. E. Hytten.

GARCIA, P., RODERUCK, C. and SWANSON, P. The relation of age to fat absorption in adult women together with observations on concentration of serum cholesterol. *J. Nutrition*, 1955, **55**, 601-609. [Dept. Home Econ. Res., Iowa Agric. Exp. Stat., Ames.]

The subjects were 58 apparently normal women aged from 30 to 90 years; at least 10 were from each decade of age, except that only 3 were aged 80 to 90. The women were given a standard test meal containing 0.5 g. oleomargarine per kg. body-weight. Blood samples were taken before the test meal and subsequently hourly for 7 hr. Fat absorption was studied by estimation of chylomicron concentrations; serum cholesterol was also estimated.

With advancing age the maximum number of chylomicrons appearing in the blood after the test meal rose, as did the time interval before the maximum count was obtained. Serum cholesterol values rose with age up to the seventh decade and then fell; thus, serum cholesterol values may not be related to the pattern of fat absorption.

5269

HOLASEK, A. Über den Ursprung des Kotfettes. 2. Versuche an Ratten mit Gallengangverschluss. [Origin of faecal fat. 2. Experiments on rats with ligated bile duct.] 3. Versuche an Menschen. [3. Experiments on man.] *Hoppe-Seyler's Ztschr.*, 1954, **298**, 219-223; 224-229. [Med. Chem. Inst., Univ. Graz.] For part 1 see Abst. 2274, Vol. 25.

2. After a control study on fat-free diet, the bile duct in adult rats was ligated in 2 places and cut. Rats which survived for a week then received the fat-free diet for 3 to 5 weeks; those with poor appetite were not used.

After operation the content of higher fatty acids in the faeces was double or treble that before operation, but it fell to normal when the rats were given agar and terramycin. The faecal flora was mostly Gram-negative. It is concluded that the

increase in fat excretion after operation was due to increased bacterial growth in the intestine.

3. The 5 subjects received the same diets, but ate different amounts. The diet was high in vegetable products and only plant fat was used.

The amounts of higher fatty acids in the faeces were reduced to about 20 per cent. of their normal when the subjects took by mouth terramycin and chloramphenicol or terramycin and streptomycin.

It is concluded that in man also, much of that faecal fat which is not of dietary origin is bacterial.

D. Duncan.

TASKER, R. R. Neutral fat absorption in the rat. The alleged effect of choline and the changes in the intestinal lymph. *Canad. J. Biochem. Physiol.*, 1955, **33**, 361-367. [Banting and Best Dept. Med. Res., Univ. Toronto, Ont.]

The intestinal lymph ducts of rats were cannulated. The rats were then starved for 24 or 48 hr., and each received by stomach tube 1 ml. olive oil; 10 received also 1 ml. of 1 per cent. choline chloride solution, 5 received 1 ml. distilled water and 7 received 1 ml. saline isotonic with the choline solution. Lymph was collected before and for 48 hr. after the test meal for estimation of total lipids and phospholipins.

The effect of choline in increasing the rate of fat absorption was small and probably not significant, and there was no effect on absorption of phospholipins.

The effect of the fat meal was an increase in the hourly lymph output, with a peak in 2 to 3 hr. and no change in fat-free dry matter content. The total fat and phospholipin contents reached their peaks in 4 or 5 hr. Total lipids rose and fell more rapidly than phospholipins.

The results are at variance with those of Frazer (Abst. 746, Vol. 16).—D. Duncan.

FISCHER, W. and KIMBEL, K. H. Untersuchungen über enterale Antibiose bei der Ratte. 6. Wirkung auf die Fettersorption. [Studies on intestinal antibiotics in the rat. 6. Effect on fat absorption.] *Ztschr. ges. exp. Med.*, 1954-1955, **125**, 437-444. [Med. Klin., Univ. Erlangen.] For earlier parts see Absts. 4382, Vol. 24; 2215, Vol. 25.

The adult rats received a low-fat basal diet of defatted casein, glucose, the known vitamins and salt mixture. After 19 days they were given an olive oil supplement. After 17 weeks they were divided into 2 groups and given 25 mg. terramycin or aureomycin daily for another 9 weeks; the fat was then withdrawn for the last 15 days. Faecal fat and free fatty acids were estimated.

The output of neutral fat fluctuated little throughout the experiment. During the pre-

liminary period on fat-free diet the free fatty acid output was about 22.5 mg. daily, but when olive oil was given it rose sharply and remained at about 180 mg. daily for the next 17 weeks. When terramycin was given there was first a sharp drop in fatty acid excretion, but after a week it had risen again to about 149 mg., where it remained fairly steady as long as olive oil was given. With aureomycin the initial sharp fall also occurred, followed by a rise, but a week later the output became stabilised at the lower level of 90 mg. When the olive oil was withdrawn the fatty acid output in both groups fell to 21 mg. daily, nearly the same as in the preliminary period.

The antibiotics had no effect on faecal neutral fat, which was independent also of diet. The effect of aureomycin on the free fatty acid was significant, that of terramycin was not significant in individual animals.—D. Duncan.

LABECKI, T. D., BRIGHT, I. B., LAKE, W. W. and THOMPSON, C. C. **Effect of a therapeutic regime on hyperchylomicronemia and hypercholesterolemia.** *Amer. J. Clin. Nutrit.*, 1955, **3**, 141-147. [Heart Dis. Control Unit, Mississippi State Board Health.]

A commercial mixture of lipotropic substances, "Methischol" was given to 11 patients with myocardial infarction and to 24 normal white women of average age 77 years for 9 or 12 weeks. The average daily intake of lipotropic substances was choline dihydrogen citrate 2 g., methionine 800 mg. and inositol > 600 mg. Total and ester serum cholesterol were estimated and chylomicron counts were made at intervals.

After 9 weeks the total serum cholesterol of the patients with myocardial infarction showed a decrease of "borderline" statistical significance; this decrease was not observed in the (presumably) non-atherosclerotic women.

All subjects given the lipotropic mixture showed a statistically significant depression of chylomicron levels.—G. A. Garton.

MORRIS, B. **The interrelationships of the plasma and lymph lipid fractions before and during fat absorption.** *Austral. J. Exp. Biol. Med. Sci.*, 1954, **32**, 763-782. [Kanematsu Mem. Inst. Pathol., Sydney Hosp.]

Cats, rabbits and rats were used in a study of lipid fractions of lymph and plasma. In the post-absorptive state, the concentration of lipids in the circulating plasma of cats was greater than that in the thoracic duct lymph. The concentration gradient between the lipids of plasma and lymph was similar to that of the plasma and lymph globulins.

The total fatty acids, phospholipins and cholesterol in lymph increased during fat absorption. The fat recovered from the lymph of unanaesthetised rats during 10 hr. after ingestion of 1 ml. olive oil accounted for 41 to 79 per cent. of the amount given. In similar experiments only 6 to 21 per cent. was recovered from cat lymph in 10 hr. after intake of 3 ml. olive oil per kg. bodyweight, and 0.5 to 2 per cent. in 10 hr. from rabbits.

The phospholipins recovered from thoracic duct lymph during 10 hr. were estimated to be up to 10 times the total amount of circulating plasma phospholipins in the rat and about 50 per cent. of that in the cat and the rabbit. The possible significance of intestinal mucosa as a source of plasma phospholipins is discussed.—G. A. Garton.

5276

MORRIS, B. and COURTICE, F. C. **Lipid exchange between plasma and lymph in experimental lipaemia.** *Quart. J. Exp. Physiol.*, 1955, **40**, 149-160. [Kanematsu Mem. Inst. Pathol., Sydney Hosp.]

High blood fat levels were produced in 2 groups of rabbits, one group given cholesterol 2 g. in the diet on 3 days weekly for 12 to 14 weeks, the other group repeated intravenous injections of 2.5 ml. per kg. of 20 per cent. Tween 80 in saline. Subsequently blood samples were taken from the femoral vein and lymph was collected from a cannula in the thoracic duct. Plasma and lymph were examined by zone electrophoresis and analysed for total cholesterol, lipid P and total esterified fatty acid.

In animals given cholesterol, plasma cholesterol increased 11-fold, but phospholipins and total esterified fatty acids only doubled; the concentrations of these lipids increased in thoracic duct lymph, but relatively less than in plasma. The phospholipin: cholesterol ratio fell from 2.2 to 0.4 in plasma and from 2.4 to 0.7 in lymph. The injection of Tween 80 caused a 5- to 6-fold increase

in all the plasma lipid fractions; lymph lipids increased 2 or 3 times. No significant change occurred in the phospholipin: cholesterol ratio in plasma or lymph.

The animals given cholesterol had high plasma concentrations of cholesterol-containing lipoprotein which migrated electrophoretically behind and with the β -globulin; similarly increased amounts of large-molecular lipoproteins were found also in plasma of the animals treated with Tween 80. The amount of lipoproteins and particulate lipids in lymph was much less than in the plasma in both groups.—G. A. Garton.

TEPPERMAN, H. M. and TEPPERMAN, J. (with DEWITT, J. M.) Ketogenesis in rats on high carbohydrate and high fat diets. *Amer. J. Physiol.*, 1955, 180, 511-518. [Dept. Pharmacol., State Univ. New York.]

Adult rats were given to appetite for 4 to 6 weeks high-carbohydrate or high-fat diets of similar energy value. The diets (Abst. 5210, Vol. 19) were modified to include casein instead of lactalbumin and gelatine as protein source; about 20 per cent. of the energy was contributed by protein and most of the rest by fat or carbohydrate; lard was used instead of maize oil in the high-fat diets. After 4 to 6 weeks the animals were killed and liver slices were prepared for the study of oxygen consumption and ketone body production.

The blood ketone content of rats given the high-fat diet was significantly higher than that of rats given the high-carbohydrate diet, but when the animals were fasted for 24 hr. the reverse was true. Surviving liver slices from fat-fed rats produced more ketone bodies than did comparable slices from the carbohydrate-fed rats; after a 24-hr. fast, the reverse was true. The addition of octanoate did not affect the capacity of liver slices from fat-fed rats to oxidise octanoic acid. Washed liver particles from livers of fat-fed rats consistently showed a low capacity to oxidise octanoate, but no impairment of ketoglutarate oxidation. Fortified whole homogenates from the livers of the rats on either diet were differentiated by either an increased production of ketone bodies by homogenates from fat-fed rats or by a smaller increment in both oxygen consumption and ketone production on addition of octanoate to the same homogenates.

MENG, H. C. and YOUNG, J. B. Utilization of a "synthetic" triglyceride preparation by weanling rats. *J. Nutrition*, 1955, 55, 527-541. [Dept. Physiol., Sch. Med., Vanderbilt Univ., Nashville, Tenn.]

Groups of weanling rats were fed for 13 weeks on diets containing 5 or 25 per cent. lard or a synthetic triglyceride composed of oleic acid 60-0, palmitic acid 30-0, stearic acid 7-4 and linoleic acid 2-6 per cent. Weights of animals were recorded weekly and water and N balances were studied; faecal fat was estimated.

The synthetic fat was utilised well for growth, especially at the 25 per cent. level. The average daily weight gains per rat for the groups fed on diets containing 5 per cent. lard, 25 per cent. lard, 5 per cent. synthetic fat and 25 per cent. synthetic fat were 3-18, 3-45, 2-91 and 3-27 g., respectively. From 94-6 to 98-6 of the synthetic fat eaten was absorbed.—G. A. Garton.

5284

SILBERBERG, R. and SILBERBERG, M. Life span of mice fed a high fat diet at various ages. *Canad. J. Biochem. Physiol.*, 1955, 33, 167-173. [Snodgrass Lab., St. Louis City Hosp. Div., Mo.]

Male mice of the C57 BL strain were studied. One group of 100 mice received a stock diet of

Purina Laboratory Chow throughout life and another group of 76 received from 1 month of age the diet with 29 per cent. fat, which was prepared by grinding the chow to a meal and adding 25 per cent. lard. Another 61 mice were given the high-fat diet from 6 months of age, and 39 from 12 months. Further groups of 65, 51 and 49 mice were given the high-fat diet for 5 months starting at ages one month, 7 months and 12 months, respectively. At all other times the mice were given the stock diet; both stock diet and high-fat diet were given to appetite, with water always available. Only 225 of the animals, which died or had to be killed because of sickness, are included in this study.

The most frequent cause of death was chronic kidney disease and anaemia. The high-fat diet given from 6 or 12 months shortened life, but less than when the diet was given from one month. Old mice were more susceptible to the adverse effect on life span than young adult mice. When the high-fat diet was given for 5 months to growing mice it had no effect on life span; given to young adults it had a beneficial effect, but in old animals it slightly shortened life.—G. F. Garton.

FISCHER, W. and KIMBEL, K. H. Die Nahrungs-fettbilanz der Ratte. [Dietary fat balance in the rat.] *Ztschr. ges. exp. Med.*, 1954-55, 125, 426-436. [Med. Klin., Univ. Erlangen.]

Rats weighing 180 to 200 g. received for 48 hr. a low-fat basal diet, consisting of extracted casein with 0.3 per cent. fat, 2 g. daily, glucose 8 g., salt mixture 0.4 g., a vitamin mixture, and water as desired. The rats then received 2 g. olive oil by stomach tube and faeces were collected every 4 hr. for 48 hr. for estimation of free fatty acids and neutral fat.

The peak of excretion of free fatty acid and neutral fat occurred 24 hr. after the fat meal and was over within 40 to 44 hr. On the low-fat diet, which provided about 25 mg. fat daily, mean daily excretion was 81.5 mg., of which 20.5 mg. represented free fatty acids. In the 48 hr. after a meal of 2 g. olive oil the mean total fat excretion was 243.5 mg., 178 mg. of free fatty acid. After 4.5 g. olive oil the values were 481 and 397 mg. The mean absorption was 91 ± 4 per cent. Neutral fat excretion was constant within the limit of statistical variation, or only slightly increased with the highest fat intake.—D. Duncan.

5286

KAUNITZ, H., SLANETZ, C. A. and JOHNSON, R. E. Antagonism of fresh fat to the toxicity of heated and aerated cottonseed oil. *J. Nutrition*, 1955, 55, 577-587. [Dept. Pathol., Columbia Univ., New York.]

Vol. 25, No. 4

Albino rats, 4 weeks old when the study began, were fed on a diet containing 15 to 20 per cent. of refined cottonseed oil which had been heated to 95° C. for 200 to 300 hr. The animals lost weight rapidly and death ensued within 3 weeks; the affected animals had diarrhoea, and post-mortem examination revealed large livers, kidneys and adrenals and small spleens and thymus glands. The only lesion apparent histologically was occasional intestinal oedema.

The administration of DL- α -tocopherol did not much alleviate the condition, but the toxicity of the heated oil was prevented by fresh cottonseed oil mixed in the diet, though the retardation of growth persisted. The protective effect of fresh oil was not as marked when it was given separately, not mixed with the rest of the diet, and so it is concluded that the protective effect is probably not due to an antimetabolite relationship, but perhaps to a change in the state of polymerisation of the heat-treated oil.—G. A. Garton.

5287

CHENG, A. L. S., GRAHAM, T. M., ALFIN-SLATER, R. B. and DEUEL, H. J. (Jr.) The effect of fat level of the diet on general nutrition. 15. Comparison of the protective effect of linoleic acid and linolenic acid against multiple sublethal doses of X-irradiation in the rat. *J. Nutrition*, 1955, 55, 647-653. [Dept. Biochem., Sch. Med., Univ. S. California, Los Angeles.]

Male rats were given a fat-free diet from weaning to 6 weeks of age. While continuing to receive the same diet, the animals were divided into groups of 13 or 14 and the diet was supplemented twice weekly for 19 weeks with ethyllaurate 0.25 ml., methyl linoleate 10, 20, 40 or 80 mg., ethyl linolenate 10, 20, 40 or 80 mg., or a mixture of methyl linoleate and ethyl linolenate 10 mg. each. Two weeks after the supplemented diets were withdrawn the rats were exposed to 200 r of X-rays weekly for 7 weeks, after which they were under observation for a further 10 weeks. Bodyweights were recorded regularly and the average survival time and percentage mortality in each group were noted.

Compared with the control group given ethyl laurate, the administration of methyl linoleate protected the rats against X-ray injury; the average survival time was almost twice that of the control group. Linolenate alone afforded only slight protection, but at the 10 mg. level with linoleate the protective action was such as to suggest that synergism exists and that linoleate may be required to initiate the action of linolenate.

HOFUND, S., HOLMBERG, J. and SELLMANN, G. Investigation on fat digestion and fat metabolism in ruminants. 1. Feeding unsaturated fats to dairy cows; fat digestion in rumen. *Cornell Vet.*, 1955, **45**, 254-261. [Dept. Cattle and Sheep Dis., Royal Vet. Coll., Stockholm.]

A lactating cow was given linseed, 1 to 2 kg. daily for 2 periods of several weeks, sunflower seed, 1 kg. daily for 16 days, and cod liver oil, 100 ml. daily for 16 days; each experiment was followed by at least 3 weeks of normal feeding. Linseed, 1 kg. daily, was given to a pregnant cow for 17 days; it calved 6 days later. Rumen activity was studied by microscopic examination of microorganisms, fermentation and nitrate disappearance tests and cellulose digestion. Milk fat and colostrum were analysed for I value, saponification equivalent and polyethenoid fatty acids.

Administration of linseed, which is rich in linolenic acid, to the lactating animal resulted in a slight increase in the linolenic acid content of the milk fat, and a considerable increase in linoleic acid and conjugated dienoic acid; increased amounts of tetra- and pentaenoic acids were also found. It is considered that hydrogenation of linolenic acid takes place in the rumen.

Administration of sunflower seed, rich in linoleic acid, caused an increase only in the linoleic acid content of milk fat. When cod liver oil was given an increase of linoleic acid, tetraenes and pentaenes in milk fat was observed; there was no reduction in the amounts of short-chain acids.

Milk fat from the cow given linseed before calving contained tetraenoic and pentaenoic acids for up to 3 weeks after calving, indicating that dietary fat is stored in depots before being utilised for constituents of milk fat.—G. A. Garton.

5291

MELNICK, D. and DEUEL, H. J. (Jr.) Biological utilization of fatty acid isomers. *J. Amer. Oil Chem. Soc.*, 1954, **31**, 63-71. [The Best Foods, Inc., Bayonne, N.J.]

A review of the literature shows that during hydrogenation of vegetable oils both positional isomers and stereoisomers of unsaturated fatty acids, some of which are intermediates in the formation of the more saturated fatty acids, are produced in appreciable quantity. The unnatural *trans*-isomers, which are more resistant to oxidation and have higher melting-point than the *cis*-isomers, can be selectively produced, as is done in the manufacture of margarine.

Microbiological assays with *Lactobacillus arabinosus*, which can utilise oleic acid instead of biotin for growth, showed that oleic acid and 4 of its *cis*-isomers had about the same activity. Of 7 *trans*-isomers of oleic acid only elaidic acid, the stereoisomer, could effectively replace biotin.

Studies with rats showed that fatty acids with conjugated double bonds were not antimetabolites for the essential fatty acids, but were readily metabolised.

The essential fatty acids in vegetable oils decrease during hydrogenation, but the formation of linoleic acid isomers which have essential fatty acid activity makes hydrogenated fat compare favourably with a natural fat of comparable hardness.—A. Hepburn.

BATES, M. W., NAUSS, S. F., HAGMAN, N. C. and MAYER, J. Fat metabolism in three forms of experimental obesity. Body composition.

BATES, M. W., MAYER, J. and NAUSS, S. F. Acetate incorporation. Fatty acid turnover. *Amer. J. Physiol.*, 1955, **180**, 301-303; 304-308; 309-312. [Dept. Nutrit., Harvard Sch. Pub. Health, Boston, Mass.]

Total carcass fat was extracted from 2 groups of obese mice and 1 group of obese rats. The mice were of the genetically obese-hyperglycaemic strain or were rendered obese by injections of goldthiogluco-; rats were made obese by surgical lesions of the hypothalamus. Compared with appropriate control animals, more than 90 per cent. of the increased weight of obese animals in all 3 groups was accounted for as deposited fat. The fat accumulated in obesity was chemically similar to that found in non-obese animals. Obese animals did not show an increased total protein content.

Acetate labelled with ^{14}C was incorporated in the diet of groups of obese mice and rats similar to those used in the study reported above. The retention of ^{14}C in carcass and liver fat was studied in groups of underfed animals and in animals which were allowed to maintain weight. When losing weight, obese-hyperglycaemic mice and rats with lesions of the hypothalamus retained more ^{14}C in carcass lipids than did the corresponding control groups; the mice treated with goldthiogluco-

N.A. and R., October 1955

retained the same amount of ^{14}C in carcass lipids as did their control animals. All obese animals, when maintaining weight, retained more ^{14}C in carcass lipids than did the corresponding control groups.

Palmitic acid labelled with ^{14}C in the carboxyl group was given to groups of obese mice. The decline in ^{14}C content of the carcass lipids when the animals were gaining weight was then studied. The 2 groups of obese mice mobilised half as much fat daily as did the controls. The hypothalamic rats showed a daily turnover of fat only 5 per cent. of that shown by control animals.

It is concluded that the different types of obesity are characterised by different patterns of lipid metabolism.—G. A. Garton.

5293

PARSON, W. and CRISPELL, K. R. (with VINECOUR, J.) Studies of acetate metabolism in the hereditary obesity-diabetes syndrome of mice utilizing C^{14} acetate. *Metabolism*, 1955, 4, 227-230. [Dept. Int. Med., Sch. Med., Univ. Virginia, Charlottesville.]

Seven genetically obese and diabetic mice and their 8 littermates, with average weights of 45 and 22 g., were studied. The mice were fasted for 16 hr. and then given intraperitoneally sodium acetate containing about 1 μC . of ^{14}C . Expired CO_2 was collected for 3 hr.

Obese mice excreted more CO_2 with a tendency to lower specific activity, but when bodyweight was considered the obese and control mice were found to utilise acetate equally well. The results fail to confirm those of Guggenheim and Mayer (*J. Biol. Chem.*, 1952, 198, 259) suggesting a block in utilisation of acetate in genetically obese mice.

GIACALONE, O. and RUBINO, F. Comportamento della steatosi epatica nei ratti alimentati con dieta steatogena contenente grasso di buco o grasso di maiale. [Fatty infiltration of the liver in rats fed on a diet to produce that condition, containing beef fat or pig fat.] *Arch. Fisiol.*, 1954, 54, 159-165. [Ist. Fisiol., Univ. Palermo.]

Fifty-two male rats were maintained on a diet of, per cent., sucrose 48, fat 40, casein 5, salt mixture 5 and sawdust 2, with adequate vitamins. For half the rats the fat was lard and for half beef fat. Animals were killed after 8, 16, 24, 32 and 42 days, and lipids, fatty acids and non-saponifi-

able material were estimated in the liver. The same estimations were made on 10 normal rats. All the values for the rats having the low-protein, high-fat diets were much higher than for the normal rats, and the values for those given beef fat were regularly somewhat higher than for those given lard.

The beef fat had a somewhat lower proportion of unsaturated fatty acids than the lard.

5296

HEDIN, P. A. and SCHULTZE, M. O. Maternal diet and other factors affecting the lipid content of livers of very young rats. *J. Nutrition*, 1955, 56, 129-138. [Dept. Agric. Biochem., Univ. Minnesota, St. Paul.]

The young rats used in this study were the offspring of animals which had been fed from weaning on a diet deficient in vitamin B_{12} (see Abst. 849, Vol. 17), supplemented as required with vitamin B_{12} , choline or DL-methionine, a low-fat diet containing complete vitamin requirements (ration OC_1 of Schultze, Abst. 3982, Vol. 25) or a balanced stock ration. Towards the end of pregnancy the rats were individually housed and the young were removed soon after birth or up to 21 days later. Liver lipids of the young were estimated by solvent extraction of tissue dried at 70°C . for 48 hr.

An increase in the absolute amount and concentration of liver lipids was found within 6 hr. of birth; the increase continued until after about 40 hr. lipids accounted for about 40 per cent. of the dry weight of the tissue, compared with 15 per cent. at birth. The inclusion of vitamin B_{12} , and to a less extent of choline or methionine, caused a significantly smaller increase in the amount of liver lipids, but did not prevent it.—G. A. Garton.

5297

SCHLICHT, I. Experimentelle Untersuchungen über den Ablauf der Leberverfettung bei Hunger und Sauerstoffmangel. [Experimental studies on the development of fatty liver in starvation and oxygen lack.] *Virchows Arch.*, 1954-55, 326, 568-581. [Pathol. Inst., Humboldt Univ., Berlin.]

The fat deposition in the livers of mice was graded from I, slight, to 4, severe, on inspection of sections stained with Sudan III. In 20 control mice II had no visible fat, 7 had grade I and the others grade 2 deposition.

In starved mice fat deposition began in a few hours and reached a peak on the average in 22 to 24 hr. In the next 24 hr. the stainable fat declined almost to none, but in mice starved for 60 to 80 hr. there was a second increase, usually only slight to medium. A small number of mice at this time had fat-free livers, and these were usually animals which had died, often those with the

lowest initial bodyweight. The site of deposition of the fat was commonly peripheral or central and perivascular in the first place, later diffuse or in scattered cells. In advanced starvation necrosis occurred.

Mice kept short of oxygen also within a few hours began to deposit fat in the liver, but there was no fall and secondary rise. The fat might be central or peripheral or intermediate in position to begin with, but after 6 or 7 days of extreme oxygen lack it was always central.—D. Duncan.

MCGUIRE, J. S. (Jr.) and LIPSKY, S. R. **The effects of squalene on the incorporation of acetate into plasma cholesterol in man.** *J. Clin. Invest.*, 1955, **34**, 704-710. [Dept. Int. Med., Sch. Med., Yale Univ., New Haven, Conn.]

Eight subjects with limited expectancy of life were used in this study. All were given 200 μ C. of Na acetate-1-¹⁴C by mouth. The acetate was given to 3 of the subjects on the fourth day of a 5-day period during which 25 g. squalene was given daily by mouth; 3 other subjects were given 25 g. squalene daily by mouth for 5 days, beginning 72 hr. after the acetate had been given. Blood samples were taken at intervals beginning 1 hr. after the administration of acetate and continuing for up to 29 days; the specific activity of free and ester plasma cholesterol was measured.

When labelled acetate was given in the middle of the period during which squalene was administered, synthesis of ¹⁴C-labelled plasma cholesterol was reduced to between one-half and one-third. It is suggested that this effect was probably due to dilution of a pool of metabolic intermediates between acetate and cholesterol.—G. A. Garton.

FRIEDMAN, M. and BYERS, S. O. (with GUNNING, B., OMOTO, C. and HAYASHI, W.) **Observations concerning the production and excretion of cholesterol in mammals. 14. The relationship of the hepatic reticulo-endothelial cell (Kupffer cell) to endogenously produced cholesterol.** *Circulation*, 1954, **10**, 491-500. [Harold Brunn Inst., Mount Zion Hosp., San Francisco, Calif.] Spanish summary.

For earlier papers of the series see Absts. 4843, Vol. 24 and 2296, Vol. 25.

Injection of India ink, which accumulated in the reticulo-endothelial cells, did not affect the cholesterol content of the bile of rats.

Serum rich in cholesterol was obtained from rats with ligated bile ducts, given 200 mg. cholate daily with a sterol-free diet. The serum was centrifuged to remove chylomicrons and then injected into 10 rats which were killed 6 or 24 hr. later, 1 hr. after injection of India ink. Other rats were given cholesterol by mouth, and 3 controls were starved for 24 hr. and given no cholesterol. The cholesterol given in serum produced lipid accumulation within the liver parenchymal cells, but not between the cells or in the reticulo-endothelial cells; the cholesterol given by mouth produced lipid accumulation mainly between the parenchymal cells and in or around the reticulo-endothelial cells. In rats given India ink injections twice daily for 48 hr. there was no effect on deposition of cholesterol injected in serum, but deposition of cholesterol given by mouth was much reduced.

In rats similarly injected with India ink for 48 hr. cholesterol given by mouth produced high blood cholesterol, moderate turbidity and many chylomicrons, but cholesterol given as serum did not. The presence of chylomicrons in injected

serum also appeared to interfere with removal of dietary cholesterol by the liver, by blocking the reticulo-endothelial cells.

It is suggested that dietary cholesterol and that formed endogenously are removed from the blood in different ways and are in different physicochemical states.—D. Duncan.

HOTTA, S. and CHAIKOFF, I. L. The role of the liver in the turnover of plasma cholesterol. *Arch. Biochem. Biophys.*, 1955, **56**, 28-37. [Dept. Physiol., Sch. Med., Univ. California, Berkeley.]

Cholesterol-4-¹⁴C was injected intravenously into male rats and blood samples were withdrawn at intervals from 18 to 90 hr. after the injections; cholesterol was isolated from the plasma and its specific radio-activity was measured.

When plotted on semilogarithmic paper, the specific activity-time curves for total plasma cholesterol were straight lines, characteristic of a single homogeneous pool of cholesterol; the turnover time was about 60 hr.

Similar experiments were made on animals in which the hepatic artery had been severed; this resulted in an almost complete cessation of the decline in the specific activity-time curves, indicating that the liver is the main site of formation and destruction of cholesterol.—G. A. Garton.

WEISS, S. B. and MARX, W. The fate of radio-active cholesterol in mice with modified thyroid activities. *J. Biol. Chem.*, 1955, **213**, 349-353. [Dept. Biochem. Nutrit., Sch. Med., Univ. S. California, Los Angeles.]

Groups of hyper- and hypothyroid mice received intravenous injections of 4-¹⁴C-cholesterol. The animals were then caged separately for 48 or 96 hr. and the excreta were collected. The mice were killed and total carcass cholesterol and saponifiable fractions were isolated and tested for ¹⁴C activity. It was concluded that thyroid can stimulate the conversion of cholesterol to acidic products as well as the excretion of the sterol and some of its acidic metabolites.—G. A. Garton.

KANTIENGAR, N. L. and MORTON, R. A. Formation of cholesta-3:5-dien-7-one in rats. *Biochem. J.*, 1955, **60**, 28-29. [Dept. Biochem., Univ. Liverpool.]

Adult rats were fed for 60 days on a diet containing 2 per cent. cholesterol; controls received the same diet without cholesterol. The liver lipids were extracted and assayed for vitamin A; unsaponifiable matter was chromatographed on

alumina and the resulting fractions were examined spectrophotometrically.

Cholesterol reduced the liver store of vitamin A from 607 to 305 I.U. per g. Control animals showed only a trace, < 0.06 mg., of cholesta-3:5-dien-7-one in the liver; cholesterol-fed rats had 0.6 mg. 7-Dehydrocholesterol was present in greater amounts in the livers of the rats given cholesterol than in the controls.—G. A. Garton.

KANTIENGAR, N. L. and MORTON, R. A. The administration to rats of cholesta-3:5-dien-7-one. *Biochem. J.*, 1955, **60**, 30-34. [Dept. Biochem., Univ. Liverpool.]

Adult rats were given from 25 to 100 mg. cholesta-3:5-dien-7-one daily either dissolved in arachis oil or mixed with the diet. Examination of liver, faecal and intestinal lipids showed that the sterol was slowly and incompletely absorbed. Most of that absorbed could not be accounted for, though some of it was probably isomerised to give cholesta-4:6-dien-3-one which was subsequently reduced to cholesta-4-en-3-one. Some was converted to digitonin-precipitable steroids and other constituents of faecal unsaponifiable matter. Small amounts of impure dienes were isolated from the liver.—G. A. Garton.

5309

KANTIENGAR, N. L., LOWE, J. S., MORTON, R. A. and PRY, G. A. J. The effects of administering cholesterol and cholesta-3:5-dien-7-one to cockerels. *Biochem. J.*, 1955, **60**, 34-39. [Dept. Biochem., Univ. Liverpool.]

Cockerels were given a diet containing either 2 g. cholesterol or 0.33 g. cholesta-3:5-dien-7-one daily from the 8th to the 16th week of age. Control birds received the same diet unsupplemented.

Blood cholesterol for control and diene-fed birds remained between 105 and 152 mg. per 100 ml.; those given cholesterol had values of 526 to 860 mg. per 100 ml.

Cholesta-3:5-dien-7-one was poorly absorbed and no effect on the unsaponifiable matter, cholesterol or vitamin A content of liver was found; the intestines were heavier than those of the controls and contained more unsaponifiable matter, including cholesterol.

Cholesterol feeding induced fatty livers with a tenfold increase in unsaponifiable matter. Much liver vitamin A was lost. Cholesta-3:5-dien-7-one was found in liver and intestinal unsaponifiable matter. The livers of all cockerels contained a substance showing λ_{max} 272 m μ . in light petroleum; an associated substance gave an absorption band near 315 m μ . in concentrated H₂SO₄.

Rabbits receiving daily 15 to 50 ml. of cream containing 36 per cent. fatty acids in 7 to 10 days showed increases in the blood neutral fat, phospholipins and total cholesterol. When the total esterified fatty acids in the blood appreciably exceeded 20 to 30 m. equiv. per litre there was a steep rise in their ratio in the neutral fat, diarrhoea occurred with high blood sugar and N and the rabbits died. No deposit of lipids was found in the aorta, large arteries or other important viscera, except the liver after 40 to 180 days on cream. In sharp contrast to the results described in part 2 (Title 3508, Vol. 10), when cholesterol was given to rabbits a large increase occurred in the blood cholesterol, but only a small increase in the neutral fat, and lipid was deposited in the aorta, arteries and other tissues.—A. Hepburn.

McMILLAN, G. C., HORLICK, L. and DUFF, G. L. Cholesterol content of aorta in relation to

severity of atherosclerosis : studies during progression and retrogression of experimental lesions. *Arch. Pathol.*, 1955, 59, 285-290. [Dept. Pathol., Pathol. Inst., McGill Univ., Montreal.]

Cholesterol was given to 101 rabbits on 6 days a week for 90 days ; each rabbit received daily 93 g. rabbit pellets coated with 6 g. maize oil and 1 g. cholesterol. After this time 39 rabbits were killed and the rest received pellets alone for from 2 weeks to 6 months ; groups of 4 to 6 were killed every 2 weeks. Another 17 rabbits had 0.5 cholesterol daily for 6 weeks, then 1 g. daily for 6 weeks, and were killed after 19 weeks on stock diet. Seven controls were killed after 2 months on the pellet diet. Aortas were examined visually for atherosclerotic lesions and their cholesterol content was estimated.

The cholesterol content of the aorta did not decrease even after 6 months on the cholesterol-free diet. Atherosclerotic lesions after 2 or 3 months or longer showed an apparent morphological regression with fibroblastic proliferation, but it is considered that there was no true regression. There was only crude and variable correlation between the visual grading of atherosclerotic lesions and the cholesterol content of the aorta. It is suggested that both methods of assessment are subject to large errors.—D. Duncan.

BLOMSTRAND, R. and RUMPF, J. A. The conversion of [^{14}C] cetyl alcohol into palmitic acid in the intestinal mucosa of the rat. *Acta*

N.A. and R., October 1955

physiol. scand., 1954, **32**, 374-383. [Dept. Physiol. Chem., Univ. Lund.]

[^{14}C] Cetyl alcohol was given by stomach tube to rats with thoracic duct cannulae and lymph was collected for 24 hr. The whole digestive tract was then removed and, together with faeces passed, was hydrolysed with KOH and the resulting fatty acids were extracted. Lymph lipids were fractionated on silicic acid.

From 63 to 96 per cent. of the ^{14}C given was absorbed; 31 to 64 per cent. of the activity absorbed was recovered from the thoracic lymph

lipids. About 80 per cent. of the lymph lipid activity was present as neutral fat fatty acids, mainly palmitic, and about 15 per cent. was recovered as unchanged cetyl alcohol.

It is concluded that oxidation of cetyl alcohol to palmitic acid took place during the passage of lipids through the intestinal mucosa.

SOGNNAES, R. F., SHAW, J. H. and BOGOROCH, R. **Radiotracer studies on bone, cementum, dentin and enamel of rhesus monkeys.** *Amer. J. Physiol.*, 1955, **180**, 408-420. [Harvard Sch. Dent. Med., Boston, Mass.]

Three methods of exposure to ^{131}I , ^{42}K , ^{32}P , ^{24}Na and ^3H were studied in 26 monkeys kept under an anaesthetic for periods of from 5 min. to 5 hr. The isotope was (1) injected intravenously

and allowed to reach bones and teeth through both blood circulation and saliva, (2) injected intravenously while the molar crowns were surrounded by cups fitted as described by Sognnaes and Shaw (*J. Amer. Dent. Assoc.*, 1952, **44**, 489) and containing non-radioactive saliva, or (3) applied only externally by being added to saliva in such cups. Supplies of saliva were obtained by stimulation of other monkeys with pilocarpine. Radio-activity was measured in different bones and tissues and in cement, dentine and enamel of teeth.

With method 1 the order of functioning tissues with decreasing uptake of P was alveolar bone, calvarium, shaft of long bone, cement, internal dentine, external enamel, external dentine and internal enamel. In mesenchymal hard tissues activity was highest in layers with cellular and vascular environments. In unerupted teeth uptake of P was high and comparable with that of long bones. For I no similar gradient in uptake by hard tissues was found.

With method 2 gradients within dentine and enamel were studied in comparison with data from method 1. The uptake of P by enamel in the first was 5 times that in the second method, but uptake by dentine did not differ with the 2 methods. The distribution of I was fairly uniform in both enamel and dentine. For Na and K the secretion in saliva influenced uptake by enamel, but not that by dentine.

For a comparison of the second and third methods the isotope chosen was ^{131}I . With method 3 uptake by the external layer of enamel was high; it was progressively lower towards internal layers. Uptake by dentine was less than by enamel, with only a minor gradient in its layers. With method 2 the distribution was the opposite, with only low activity in the enamel and a slight decrease towards its outer surface.

The findings are discussed with suggestions for further studies.—D. Harvey.

PATTON, M. B. Further experiments on the utilization of calcium from salts by college women. *J. Nutrition*, 1955, 55, 519-526. [Dept. Home Econ., Ohio Agric. Exp. Stat., Columbus.]

The subjects were 9 college women and the basal diet was similar to that used earlier (Abst. 3248, Vol. 23), except that the Ca content was reduced to 300 mg. daily. The Ca supplements for the 3 groups were milk, calcium gluconate and calcium carbonate, supplying 305, 208 and 208 mg. Ca daily.

The study lasted 8 weeks, but the first week was the adjustment period and the second the basal period.

There was no significant difference in utilisation of Ca between the 3 groups, but balances differed significantly from week to week, though not so much in the last 2 weeks. B.M.R. was inversely related to retention of Ca, in contradiction of the earlier experiment.

In all subjects but one the B.M.R. was lower at the end than at the beginning of the experiment, and in 7 subjects the Ca retention was highest in the last 2 weeks.—D. Duncan.

5327

STALDER, G. Phosphat-Clearance im Kindesalter. [Phosphate clearance in childhood.] *Ann. paediat.*, 1955, 184, 191-205. [Kinderspital, Basle.] English and French summaries.

The subjects were 5 infants aged 8 days to 3½ months, including 2 prematures, fed on breast milk; 5 infants aged 3 weeks to 11 months, including 2 prematures, fed on cow's milk; 4 children 4½ to 14 years old; and 5 sick children. Inulin clearance and inorganic P concentrations of the plasma and urine were studied before and after injection of parathyroid extract.

P excretion and endogenous P clearance were low in breast-fed and high in bottle-fed infants, and somewhat lower in older children than in bottle-fed infants.

The mean percentage re-absorption of filtered P in these 3 groups was 97, 78 and 90. After

injection of parathyroid hormone there was increased loss of P, increased P clearance and reduced tubular re-absorption, but no characteristic change in plasma P. The maximum re-absorption of P (Im_p) was high in 2 infants with high serum phosphate, suggesting impaired parathyroid function. It was very low in an 18-year-old girl with vitamin-D-resistant rickets and low serum P.—D. Duncan.

CAUSERET, J. and HUGOT, D. Utilisation physiologique comparée du phosphore et du calcium du lait et du yoghourt. [Comparative physiological utilisation of phosphorus and calcium of milk and yoghurt.] *Lait*, 1955, 35, 129-132. [Lab. Physiol., Inst. Nat. Recherche Agronom.]

Groups of from 3 to 6 rats of bodyweight 60 to 80 g. received for 10 days either pasteurised whole milk or yoghurt prepared from the same milk, with the addition of 20 g. sucrose per 100 g. milk or yoghurt. Calcium and phosphorus balances were studied.

In each of 3 experiments the net utilisation of both Ca and P was significantly less from yoghurt than from milk, but the extent of the difference varied. Still, yoghurt is probably better than cheese as a source of both elements.—D. Duncan.

5330

HOUSE, W. B. and HOGAN, A. G. Injury to guinea pigs that follows a high intake of phosphates. The modifying effect of magnesium and potassium. *J. Nutrition*, 1955, 55, 507-517. [Dept. Agric. Chem., Coll. Agric., Univ. Missouri, Columbia.]

In 3 series of experiments 6, 4 and 4 groups of male and female guineapigs were given different diets, all of which contained casein 30 g., soya bean oil 4 g., magnesium oxide 0.55 g. and potassium acetate 2.74 g., with vitamins A, D, C, E and those of the B group. In the first series the 6 diets all contained gum arabic as bulk and varied in their Ca and P content. There was no death and weight gains were similar in all groups. When the diets contained small amounts of Ca and P the appearance of wrist stiffness was delayed until about 23 weeks; when the diets contained less than one part of Ca to one of P stiffness developed quickly and when large amounts of Ca

and P were present and the Ca : P ratio was high the stiffness developed more slowly than when the diets contained an excess of P.

In the second and third series gum arabic and cellu flour were compared as sources of bulk and the effects of adding Mg and K were studied; the Ca : P ratios in the 2 series were 1 : 1 and 0.5 : 1. When the ratio was 1 : 1, but not otherwise, gum arabic gave better growth than cellu flour and prevented deposition of calcium phosphate. With both Ca : P ratios the addition of Mg and K improved growth and prevented deposition of calcium phosphate.—G. F. Garton.

COMAR, C. L., WHITNEY, I. B. and LENGEMANN, F. W. **Comparative utilization of dietary Sr^{90} and calcium by developing rat fetus and growing rat.** *Proc. Soc. Exp. Biol. Med.*, 1955, **88**, 232–236. [Univ. Tennessee—Atomic Energy Commission Agric. Res. Programme, Oak Ridge.]

Rockland rat diet containing 1.9 per cent. Ca was labelled with carrier-free ^{90}Sr at the rate of about 200 μC . per 500 g. diet. Young female rats were given this diet throughout pregnancy; some of their young were analysed at birth and others were reared on the same diet. Some were analysed at different stages of growth and the remaining females were divided into 3 diet groups and mated. The 3 diets were a normal stock diet, the ^{90}Sr diet and a low-Ca diet. The newborn young of the second generation were analysed.

In the rats reared on the experimental diet the utilisation of Ca was selective, and the bones of animals weighing from 70 to 400 g. showed a preferential deposition of Ca over Sr in the ratio of 3.6 : 1.

In newborn rats from females reared on the ^{90}Sr diet and therefore having uniform skeletal labelling, but fed on a normal or low-Ca diet during pregnancy, the ^{90}Sr in the body was derived from the maternal skeleton. On the normal diet it was calculated that 28.6 per cent. of the foetal Ca was derived from the maternal skeleton. Results on the low-Ca diet were less reliable because only 2 litters were obtained, but in these nearly all the skeletal Ca was of maternal origin and the ratio of 3.6 parts of Ca utilised for 1 of ^{90}Sr appeared to be valid here also. In young from dams given the ^{90}Sr diet for different periods before parturition, the preferential utilisation of dietary Ca over ^{90}Sr in foetal bone formation was in the ratio of 5.1 : 1.

ANTONI, R. and CREMER, H. D. **Ernährungsfaktoren bei Zahn- und Knochenbildung. 4. Aufnahme und Verbleiben von Ca^{45} im Organismus. [Diet components in the formation of teeth and bones. 4. Uptake and retention of ^{45}Ca in the organism.] *Biochem. Ztschr.*, 1955, **326**, 311–316. [Anorg. Chem. Inst., Johannes Gutenberg Univ., Mainz.]**

The methods were as previously described (Abst. 899, Vol. 22) except that the labelled Ca salts, in this study tertiary citrate and secondary phosphate ($\text{CaHPO}_4 \cdot 2\text{H}_2\text{O}$) and 14 : 1 and 1 : 1 mixtures of these, were given to the rats in 1 g. food after an 8-hr. fast instead of by stomach tube; almost complete recovery of ^{45}Ca was thereby achieved.

Uptake of Ca in teeth and bones from citrate was less than that previously found for lactate and chloride but was improved by a vitamin D supplement [details not given]. Mixtures of citrate and phosphate were less effective than citrate; the effect of vitamin D in conjunction with them remains to be tested.

Pairs of rats were killed from 1 to 65 days after supply of ^{45}C ceased. A gradual decline of activity in the tibia and molars set in almost at once, but in the incisors the maximum activity was reached only in the third week, no doubt owing to uptake from the blood of ^{45}Ca released by other organs.—W. M. Deans.

5334

TOMLIN, D. H., HENRY, K. M. and KON, S. K. **The interstitial metabolism of calcium in the bones and teeth of rats.** *Brit. J. Nutrition*, 1955, **9**, 144–156. [Dept. Phys., Univ. Reading.]

Twenty weanling rats in 3 groups were given a basal diet low in Ca. ^{45}Ca was added for the first group of 2 at weaning and given for 14 weeks, for the second group of 8 at 15 weeks and given for 4 weeks and for the third group of 10 at 15 weeks for 2 weeks. Rats in the first group were killed at the end of the period of feeding, those in the second in pairs after 4, 7, 14 and 28 days while the isotope was included and those in the third, also in pairs, 4, 7, 14, 28 and 70 days after it had been withheld. The method of preparation of sections of long bones and of teeth and of their autoradiographs were slight modifications of those already reported in Abst. 814, Vol. 24.

After the isotope was added equilibrium between levels of Ca in diet and serum was soon reached and was maintained so long as the isotope was

given. Quantitative measurement of the percentage uptake of interstitial Ca showed it to be at the rate of about 1 per cent. of the total cortical bone Ca per week (*cf.* earlier work, *Abst.* 2856, Vol. 23); the exchangeable fraction was small and near the limit of detection. In dentine of incisors the total interstitial uptake of ^{45}Ca was very much less than in bone. The predominant effect at the age at which observations were made is concluded to be mainly of interstitial accretion with only slight reversible exchange of Ca.—D. Harvey.

DALLEMAGNE, M. J., FARRY, C. and BODSON, P. **Exchange of bone calcium with Ca^{45} .** *Experientia*, 1955, **11**, 142-143. [*Inst. Exp. Therap.*, Univ. Liège.]

Bone ashed with glycol and KOH was exposed for a month to $^{45}\text{CaCl}_2$ and fractions of the resulting active material were exposed to different concentrations of HCl. The mineral contained 3 types of Ca ions, *i.e.*, for each 9 ions stoichiometrically bound to phosphate groups there were $1\frac{1}{2}$ ions in excess, and thirdly about 0.2 mg. per cent. of physically adsorbed Ca. Only the $1\frac{1}{2}$ excess ions and those physically adsorbed were found to be exchangeable with ^{45}Ca , and quantitatively this agreed well with the 15 per cent. exchangeability of total bone Ca reported in the literature.

MYERS, H. M. **The correlation of gain in body weight and mineral ash content of teeth and bones of rats recovering from phosphorus deficiency.** *J. Dent. Res.*, 1955, **34**, 230-238. [*Coll. Dent.*, Univ. California, San Francisco.]

Three groups of young rats were fed for 47 days on a low-P diet, an equal quantity of normal diet, or normal diet to appetite. After this the rats on the low-P diet were given the normal diet and during the next 14 days animals from each group were killed.

During recovery from P deficiency the ash weight of the femur increased more rapidly, but that of incisors less rapidly, than bodyweight. In pair-fed control rats there was no steady change in the ratio of bodyweight to femur ash weight during recovery, but the relation between incisor ash weight and bodyweight in these animals was similar to that of rats recovering from P deficiency.

MYERS, H. M. **The comparative turnover rate of P^{32} in normal and deficient rats' teeth and bones during recovery from phosphorus deficiency.** *J. Dent. Res.*, 1955, **34**, 225-229. [*Sch. Dent.*, Univ. California, San Francisco.]

Rats of the experiment described in the previous *Abst.* were given an injection of ^{32}P before they were killed, and the amounts retained in femur, incisors and molars were estimated.

The femurs of P-deficient rats retained 10.8 times as much ^{32}P as those of controls fed to appetite and 4.1 times as much as those of pair-fed controls. The incisors and molars of P-deficient rats retained not more than twice as much ^{32}P as those of either group of controls.—R. Hill.

YENDT, E. R. and HOWARD, J. R. **Studies on the mode of action of citrate therapy in rickets.** *Bull. Johns Hopkins Hosp.*, 1955, **96**, 101-115. [*Dept. Med.*, *Sch. Med.*, Johns Hopkins Univ., Baltimore, Md.]

Male Wistar rats, weighing from 40 to 55 g., were given a rachitogenic diet high in Ca and low in P for from 20 to 30 days. Some of them were then given in the diet citric acid and Na citrate to provide from 400 to 600 mg. of each. They were killed from 8 to 17 hr. later. Longitudinal slices were taken from the epiphyseal cartilage of the upper end of the tibia, and were incubated in a salt solution containing Na, K, Mg, Cl, bicarbonate and sulphate in concentrations like those in normal human serum; the concentration of inorganic P was 5 mg. per 100 ml., and that of Ca was 3.5, 4.0, 4.5, 5.0, 5.5 or 6.0 mg. per 100 ml., or higher for rats not given citrate. The slices, with some untreated slices, were stained with silver nitrate and the degree of calcification was read on an arbitrary scale with 4 degrees.

Of 24 rats not given citrate, the slices from 2 failed to calcify in any solution, and from 5 others the slices calcified in every solution. In the remaining 17 the lowest product of Ca and P at which the cartilage calcified lay between 22.5 and 37.5, most values being over 25.0.

In 8 rats given citrate in the diet, calcification occurred in solutions having a product less than 22.5. When citrate and citric acid were injected subcutaneously the immediate toxic effects prevented satisfactory study but, as far as they went, the results suggested that citrate did not exercise an antirachitic action unless it was administered through the gut.

When citrate was added to the pooled serum of infants, or to inorganic solutions shown to be capable of promoting calcification of rachitic rat's cartilage, the power to calcify was progressively

N.A. and R., October 1955

less as the concentration of citrate was increased, until it was lost altogether.

Thirteen rachitic rats were injected intraperitoneally with an isotonic solution of sodium acid phosphate and disodium phosphate in differing amounts, and the rats were killed from 1½ to 29 hr. later. Some rats were rejected as showing healing *in vivo*. Cartilage slices from the remainder calcified in solutions with products of Ca and P ranging from 15.0 to 22.5.

Estimation of serum P in rachitic rats within from 6 to 48 hr. after administration of citrate and citric acid in the diet revealed a rise sufficient to initiate the healing process.

It is suggested as a possible explanation that the action of the citrate given in the diet was to "complex" most of the dietary Ca, so that the phosphate was left free to be absorbed instead of being precipitated as Ca phosphate. Once the healing process of calcification has been initiated, it is suggested that it can continue with a product of Ca and P lower than that with which it could start.—E. M. Hume.

VAN KESSEL, H. I. A. M. Over de vernieuwings-snelheid van het anorganische fosfaat en de phospholipiden in de lever van de rat. [On the rate of turnover of inorganic phosphate and phospholipids in the liver of the rat.] *Thesis, Univ. Utrecht*, 1953, pp. 66. English summary.

In addition to the problem named in the title of this thesis, the effects on turnover of vitamin D₂ and of the intensity of combustion of fat in the body were studied. The technique for estimation of turnover by the use of ³²P and the validity of the assumption that plasma inorganic P is the precursor of liver inorganic P are discussed. Positive and negative effects of vitamin D₂ have been claimed.

Methods are described in detail. Results showed that there is no non-dialysable fraction of inorganic P in serum and that the whole of the inorganic P estimated by common methods may be considered the precursor of liver inorganic P. Short experiments lasting for from 20 to 30 min. are sufficient, with injections of ³²P, for the construction of curves of specific activity of serum and liver and the calculation of turnover.

In normal rats the rate of turnover, so measured, in liver cells is from 1.5 to 3 mg. P per hr. A 24-hr. fast approximately doubles it. Assuming the inorganic P of the liver cell to be the immediate precursor of lipid P, the rate of incorporation was about 0.2 mg. P per hr., equivalent to about 5 mg. phospholipid. A 24-hr. fast had no effect. Vitamin D₂, as 2 mg. calciferol, gave a 50 per cent. increase. These conclusions may be invalidated

when more is known of the normal variance between animals and of the intermediates formed. I. Leitch.

BLAXTER, K. L. and ROOK, J. A. F. Energy and carbohydrate metabolism in magnesium-deficient calves. *Brit. J. Nutrition*, 1955, 9, 121-132. [Hannah Dairy Res. Inst., Kirkhill, Ayr.]

Mg deficiency was produced in 4 calves with a synthetic diet (see Abst. 4877, Vol. 24). The diet was modified to cause vitamin B₁ deficiency in 2 calves, and 2 others were studied as controls.

In Mg deficiency, serum Mg fell, and heat production rose and energy retention fell in relation to the fall in serum Mg. Temporary relief was obtained by injection of MgSO₄. The increased heat production was due to increased muscle activity during tetany. Mg deficiency did not affect blood sugar, glucose tolerance, or serum phosphatase, but there were increases in blood pyruvic and lactic acid and in urine pyruvic acid.

In vitamin B₁ deficiency there was a greater increase in blood pyruvic acid. One of the calves had to be killed when the signs of vitamin B₁ deficiency became extreme, but the other improved in condition, and there was evidence of vitamin B₁ synthesis in the alimentary tract.

Exercise raised blood pyruvic and lactic acid levels of control calves to that found in Mg-deficient calves during milk tetany. This indicated that the abnormalities of energy and carbohydrate metabolism in the Mg-deficient calves were due to the increased muscular work in tetany, and not to a reduced supply of Mg to enzyme systems.

WOMERSLEY, R. A. and DARRAGH, J. H. Potassium and sodium restriction in the normal human. *J. Clin. Invest.*, 1955, 34, 456-461. [Dept. Med., Sch. Med., Yale Univ., New Haven, Conn.]

The effects on serum and urine composition of depletion of K alone or with Na were studied in 2 normal men. External balances of water and electrolytes were studied and internal balances of Na, K and water were calculated.

In all studies K depletion caused a reduction of serum K; urinary excretion of K decreased when K intake was restricted and decreased further when intakes of both K and Na were restricted.

During depletion the urine became more alkaline and the output of bicarbonate tended to rise. Balances of K were negative and when Na intake was unrestricted K depletion resulted in retention of Na and water in the extracellular space.

FOURMAN, P. and HERVEY, G. R. **An experimental study of oedema in potassium deficiency.** *Clin. Sci.*, 1955, **14**, 75-79. [Med. Res. Coun. Dept. Exp. Med., Univ. Cambridge.]

When NaCl was added to the diet of a man already depleted of K, Na and Cl were retained, there was a gain in weight and, after 3 days, oedema was detected clinically. After 6 days the volume of blood and of extracellular fluids had expanded by about 15 and 18 parts per 100, respectively. A control experiment was made by adding NaCl to the diet when the man had not been depleted of K.—F. C. Aitken.

KESSELMAN, R. H. **The formation of edema and the effect of sodium on colloid osmotic pressure.** *Amer. Heart J.*, 1955, **49**, 517-520. [Dept. Med., Women's Med. Coll. Pennsylvania, Philadelphia.] Interlingua summary.

From physico-chemical considerations an equation was derived for the relation of the colloid osmotic pressure of plasma to the concentration of Na⁺ in plasma. Over the wide range from 80 to 180 millimoles Na per litre plasma a fall in concentration was associated with a rise in pressure. From this association oedema formation should be favoured by an increase and reabsorption by a decrease in Na⁺ in plasma, a conclusion which is supported by clinical observations.—D. Harvey.

GREEN, D. M. and ELLIS, E. J. **Sodium output—blood pressure relationships and their modification by treatment.** *Circulation*, 1954, **10**, 538-543. [Sch. Med., Univ. S. California, Los Angeles.] Spanish summary.

See also Abst. 3392, Vol. 24.

The 25 subjects with normal and 50 with high blood pressure were on self-selected diets. Water and Na output in urine were estimated for 24 hr. Basal urine output was estimated in the morning after food and water had been withheld since midnight; the subject recorded the time which elapsed between the first morning urination and the second, and the volume and Na concentration of the second were estimated.

There were positive correlations between the basal and 24-hr. outputs of Na and of water; the rates of output did not differ significantly. The average 24-hr. Na secretion of 34 patients with high blood pressure was 35 per cent. higher than

that of the 25 with normal blood pressure, a significant difference. The rate of Na output after a 5 per cent. salt load was also significantly correlated with blood pressure, both before and after treatment.

Since diets were not controlled and bodyweights were stable, it is inferred that the patients with high blood pressure had an increased appetite for salt.—D. Duncan.

5347

RUNDO, J. and SAGILD, U. **Total and 'exchangeable' potassium in humans.** *Nature*, 1955, **175**, 774. [Finsen Lab., Copenhagen Ø.]

Total body K was estimated with a γ -monitor in 10 young adults of both sexes, and exchangeable K by an isotope dilution method with ⁴²K. The exchangeable K was in 9 of the subjects less than the total K by 7 to 25 per cent., mean 15.2; the experimental error in estimation of total K was so large as to swamp any possible biological variation in exchangeable K.

In one patient with typical hereditary periodic paralysis there was a much larger difference, the estimated values being 158 ± 20 g. total and 85 g. exchangeable K in the body.—D. Duncan.

LARAGH, J. H. and CAPECI, N. E. **Effect of administration of potassium chloride on serum sodium and potassium concentration.** *Amer. J. Physiol.*, 1955, **180**, 539-544. [Dept. Med., Coll. Phys. Surg., Columbia Univ., New York.]

Ten balance studies were performed on 3 dogs given a standard diet of constant electrolyte content. The effect of administration of 20 per cent. KCl solution by mouth was studied when the dogs were on a normal Na intake and also after prolonged Na restriction and after Na depletion by peritoneal dialysis.

There was a significant increase in serum Na after the administration of KCl, especially during Na restriction. This is believed to be due to release of Na ion into the extracellular space in exchange for K. There was no significant change in the balances of Na and water after administration of massive amounts of KCl; the KCl had no diuretic effect. In Na depletion there was a large and persistent increase of blood K after the administration of KCl; one of the dogs died in this experiment. The high blood K was apparently not related to incapacity to excrete K, nor was change in body fluid space critical; the Na depletion apparently limited the capacity of the animals to remove K from the extracellular fluid. The adverse effect of high blood K on cardiac muscle may be irreversible and the administration of K ion during Na depletion is therefore dangerous.

KRAKUSIN, J. S. and JENNINGS, R. B. Radioautographic localization of Na²² in the rat kidney. *Arch. Pathol.*, 1955, 59, 471-486. [Dept. Biochem., Northwestern Univ. Med. Sch., Chicago, Ill.]

Rats weighing about 200 g. received either commercial rat diet containing 38 m. equiv. Na per 100 g. or a low-Na diet with 0.42 m. equiv. per 100 g. ²²NaCl was given intravenously or intraperitoneally in doses of 5 or 10 μ C. Na and K were estimated spectrophotometrically in urine and serum and radio-activity was measured. Autoradiographs were made from kidney sections after freeze-drying.

After intraperitoneal injection equilibrium of ²²Na in plasma was reached in 30 min. and maintained for 4 hr. in normal and Na-deficient rats. In normal rats plasma ²²Na declined steadily for 96 hr.; in Na-deficient rats it remained constant. In both groups the rate of ²²Na excretion became fairly constant after from 48 to 72 hr., but it was much greater in the normal rats.

In experiments on distribution of ²²Na in the kidney, the kidney pedicles were clamped from 15 sec. to 5 min. after the start of intravenous injection of 5 μ C. of ²²Na. The ²²Na concentration first built up in the outer cortex, especially in Na-deficient rats; the outer medulla then became faintly visible and the inner medulla in about half a minute was strongly active. In animals killed 3 or 4 days after injection of ²²Na there was still

strong activity in the inner medulla, even in normal rats with very low plasma activity.

Effects of corticotropin, cortisone, deoxycorticosterone and vasopressin were not demonstrable. Organic mercurial diuretics and osmotic diuresis produced increased accumulation of ²²Na in the inner cortex of the kidney, suggesting inhibition of re-absorption of Na in the proximal convoluted tubules or in their straight portions.

The interpretation of the findings is discussed at length.—D. Duncan.

Hove, E. L. and HERNDON, J. F. Potassium deficiency in the rabbit as a cause of muscular dystrophy. *J. Nutrition*, 1955, 55, 363-374. [Dept. Animal Husb. Nutrit., Alabama Polytech. Inst., Auburn.]

Weanling rabbits weighing from 200 to 600 g. and young rabbits weighing 2000 g. were given K-deficient diets of extracted casein 20, sucrose 57, cellulose 10, lard 6, cod liver oil 2, calcium phosphate 3.6, magnesium sulphate 0.65, sodium chloride 0.55, iron citrate 0.15, manganese sulphate 0.02 and trace minerals 0.03 per cent., with vitamins E, K and those of the B group; some of the animals received 40 per cent. extracted soya bean meal in place of the casein. Different levels of K as bicarbonate were added to the basal diet. Feed and water were available to appetite. Urine samples were collected during 24 hr. three times weekly for estimation of creatine and creatinine. Blood was analysed for K and Na. At death or termination of the experiments the animals were examined for pathological conditions.

A level of 0.6 per cent. K in the diet was essential for maximum growth; with 0.3 per cent. or less death occurred within 6 weeks, usually with severe and rapidly increasing muscular dystrophy and closely associated creatinuria. Other findings were myocardial necrosis and scarring, numerous small gallbladder concretions, multiple haemorrhagic areas in the stomach, swollen, pale kidneys, occasional jaundice and atonic intestinal tract. Large supplements of Na added to the K-deficient diet produced slightly better growth, but did not prevent death and pathological signs. In K deficiency blood cell Na increased and urine Na fell.

LEVI, J. E. and SILBERSTEIN, H. E. Lack of effect of fluorine ingestion on uptake of iodine³¹ by the thyroid gland. *J. Lab. Clin. Med.*, 1955, 45, 348-351. [Dept. Med., Sinai Hosp., Baltimore, Md.]

Thirty patients who had no clinical sign of thyroid disease were given $^{50}\mu\text{C}$ of ^{131}I by mouth. Uptake of ^{131}I by the thyroid was measured every 24 hr. thereafter. After the first counts were taken, the patients were given 4 mg. fluoride ion as sodium fluosilicate in a single daily dose for the first 3 weeks and in 2 daily doses of 2 mg. each for the remaining 7 weeks. At the end of the first 3 weeks a second dose of ^{131}I was given and another uptake test was made. Only 17 of the group continued to take fluoride for the last 7 weeks until the third uptake test.

No effect on concentration of I by the thyroids was found as a result of the administration of fluoride.—B. W. Simpson.

5354

AUSKAPS, A. M. and SHAW, J. H. Hemoglobin concentration, thyroid weight and growth rate in rats during minimum fluoride ingestion. *J. Nutrition*, 1955, 55, 611-621. [Harvard Sch. Dent. Med., Boston, Mass.]

Eight groups, each of 6 male and 5 or 6 female weanling rats from 12 litters, were studied. Four groups received a purified diet (Abst. 2317, Vol. 17) and 4 a diet of natural foodstuffs, consisting of whole wheat flour 27, yellow maize meal 26.5, whole milk powder 30, maize oil with added vitamins A, D, E and K 5, crude casein with added water-soluble vitamins 9, salt mixture 2 and NaCl 0.5 per cent. The diets and water were available to appetite; 2 groups, one on each diet, received distilled water; another 2 received distilled water with NaF added to give 1 p.p.m. of fluoride, 2 received 5 and 2 had 20 p.p.m. fluoride. After 11 months the animals were killed and the extent of the caries present was estimated; fluoride was estimated in the humerus, femur and thyroid.

In all 8 groups growth and reproduction were normal. There was no depression of Hb formation, no detectable fluoride uptake by the thyroid gland, no hypertrophic change in the thyroid and no decrease in resistance to a severe respiratory infection at any level of fluoride intake. The incidence of dental caries was significantly reduced when the fluoride intake was 20 p.p.m.

HIRAO, M. [Blood picture of experimental fluorosis. 1. Changes of erythrocyte, haemoglobin, colour index, reticulocyte, blood platelet and the size of erythrocyte. 2. Influence on the leucocytes of rabbits ingesting sodium fluoride. 3. Influence on the bone marrow of rabbits ingesting sodium fluoride.] *Shikoku Acta Med.*, 1954, 5, 344-353; 370-375; 376-383. [Dept. Int. Med., Sch. Med., Tokushima Univ.] English summary.

1. Three groups of mature rabbits received NaF at rates of 10, 30 and 50 mg. F daily per kg. body-weight, and 1 group of immature rabbits at the 30 mg. rate; there was a control group at each stage of development. Those given NaF lost weight and showed signs of hyperchromic macrocytic anaemia and increases in counts of reticulocytes and blood platelets.

2. Mean weekly values for differential leucocyte counts are tabulated. Leucopenia was found in the latter half of the experiment.

3. Tables give numbers of nucleated cells and differential counts for samples of bone marrow taken at intervals of 4 weeks. The numbers of nucleated cells fell and histological examinations showed fatty marrow in the 10-mg. group and gelatinous marrow in another [not identified]. The changes in marrow were such as to produce the blood changes described. (From summaries.)

It was desired to know whether or not fluorine was taken up by the organic part of the teeth and skeleton. The organic part was obtained by decalcification of bone with HNO_3 , the inorganic part by calcination or alkaline hydrolysis. F was estimated in both fractions of beef bone, tendon and cartilage, and of bone from a kid, before and after immersion for 24 hr. at 37°C . in 3 per cent. NaF. Both fractions of all the tissues fixed fluorine to a very considerable extent.

Similar tests with adult human teeth showed that much fluorine was fixed by the organic and inorganic fractions, but more by the latter.

DUBACH, R., MOORE, C. V. and CALLENDER, S. Studies in iron transportation and metabolism. 9. The excretion of iron as measured by the isotope technique. *J. Lab. Clin. Med.*, 1955, 45, 599-615. [Dept. Int. Med., Sch. Med., Washington Univ., St. Louis, Mo.]

For part 8 see Abst. 3909, Vol. 25.

Excretion of Fe was measured in 5 normal human subjects, in 3 female patients with hypochromic anaemia and in 2 others with anaemia of haemolytic origin, one a woman with a sickle-cell anaemia and the other a man with hereditary sphaerocytosis. Estimations were made also of faecal excretion in dogs with haemolytic anaemia produced by phenylhydrazine given by mouth, and of the excretion by the skin during sweating induced in a normal man and woman and in a man with hypoplastic anaemia.

Vol. 25, No. 4

In human subjects the loss of Fe in faeces was normally about 0.5 mg. daily, and no increase in rate appeared at or near 120 days after injection of radio-active Fe, when destruction of cells incorporating it was likely to be greatest. In the patients who were deficient in Fe the excretion was less and in those with haemolytic anaemia it was greater than in the normal persons. Only minute amounts appeared in the sweat secreted by the normal or the pathological subject. In the dog during severe Hb destruction when it was estimated that 240 mg. Fe were released in the process, only about 3 per cent. of that amount was excreted.

These amounts are small but, if the total excretion by man is taken to be between 0.5 and 1.0 mg. daily, such a loss may have significance for the normal person whose intake is 15 mg. and who may be absorbing less than 10 per cent. of it.

MAZUR, A., BAEZ, S. and SHORR, E. The mechanism of iron release from ferritin as related to its biological properties. *J. Biol. Chem.*, 1955, 213, 147-160. [Dept. Med., Cornell Univ. Med. Coll., New York.]

Crystalline ferritin contained small amounts of ferrous Fe as well as free sulphhydryl groups. As oxidation or blocking of the latter decreased ferrous Fe and reduction increased it, it is suggested that the sulphhydryl groups serve to prevent the auto-oxidation of the ferrous Fe. The conversion of ferric-disulphite-ferritin to ferrous-sulphhydryl-ferritin by the liver is probably mediated by glutathione. Sulphhydryl ferritin was dissociable at pH 7.4 into ferrous Fe, which could combine with the Fe-binding protein of human plasma. Severe hypotension due to haemorrhage in dogs also produced the transfer of ferrous Fe from ferritin in the hypoxic liver to the plasma.

The vasodepressor activity of ferrous-sulphhydryl-ferritin was abolished when ferrous Fe was removed.

A hypothesis based on oxidation and reduction for the role of ferritin in Fe transport and haem synthesis is advanced.—A. Hepburn.

KALDOR, I. Studies on intermediary iron metabolism. 6. The absorption and storage of iron in experimental anaemia. *Austral. J. Exp. Biol. Med. Sci.*, 1954, 32, 801-805. [N.S.W. Red Cross Blood Transfusion Serv., Sydney.]

For previous parts see Absts. 3914, 4735, Vol. 23; 2118, 4618, Vol. 25.

Four groups of rats were on experiment for from 26 to 28 weeks; they were a control group with no treatment, a group given, for the first 16 weeks, doses of phenylhydrazine to maintain an Hb value 60 per cent. of that of the control rats and thereafter allowed to recover, a group given Fe in drinking water from the 12th to the 16th week and a group given both of these experimental treatments. At the end the rats were killed.

Means for bodyweight and liver weight were unaffected but that for spleen weight was greater in each phenylhydrazine group than in those without anaemia and greatest in the group given both treatments. Fe was estimated in blood serum, liver and spleen; its level followed the same pattern, and in the 2 tissues of the animals given Fe alone, an increase also occurred, but smaller than in the anaemic rats. Phenylhydrazine had no effect on Fe-binding capacity of serum.

It is concluded that absorption of Fe is increased both by anaemia and by an increase in intake, and it is inferred that the giving of Fe is permissible only if the anaemia is the result of Fe deficiency. In other forms of anaemia, especially if repeated blood transfusions are made, accumulation of Fe may lead to early haemosiderosis.—D. Harvey.

5366

CRISCUOLO, D., CLARK, R. T. (Jr.) and MEFFERT, R. B. (Jr.) Effects of low and high iron supplementation on hypoxic rats. *Amer. J. Physiol.*, 1955, **180**, 215-218. [Dept. Physiol. Biophys., U.S. Air Force Sch. Aviation Med., Randolph Field, Tex.]

Two groups each of 100 rats were given a diet of evaporated milk with added Mn and Cu; those in one group had 0.04, those in the other 0.4 mg. Fe daily. After 6 weeks, when the low-Fe group showed signs of anaemia, the groups were further subdivided equally, half of the animals being kept in ground level conditions and half subjected to decompression equivalent to an altitude of 20,000 ft. for 22 hr. daily for 6 weeks. At the end they were killed; weight, Hb, red blood cell count and volume, oxygen uptake by liver slices, myoglobin content of muscles and weight and ascorbic acid content of adrenals were estimated.

Survival did not differ between high altitude and ground level animals and the increase in Hb in hypoxic animals found in the high-Fe but not in the low-Fe group was concluded not to be indispensable for survival. Myoglobin and oxygen values were generally higher in altitude than in ground level rats, but the differences were not all statistically significant.—D. Harvey.

MAYNARD, L. S. and COTZIAS, G. C. The partition of manganese among organs and intracellular organelles of the rat. *J. Biol. Chem.*, 1955, **214**, 489-495. [Div. Physiol., Dept. Med., Brookhaven Nat. Lab., Upton, N.Y.]

^{55}Mn rapidly disappeared from the blood of rats and of a human subject after intraperitoneal injection of physiological amounts of Mn. In rats, tissue rich in mitochondria, liver, pancreas and kidney, had the highest concentration of the isotope. Most was found in the cell organelles; of this the mitochondria contained about 2/3. The concentration in the mitochondria was possibly related to the action of Mn as a respiratory coenzyme.—A. Hepburn.

5371

BOLTON, W. The effect of injections of oestradiol dipropionate into immature pullets upon the manganese content of the blood plasma and of some tissues. *Brit. J. Nutrition*, 1955, **9**, 170-173. [Poultry Res. Centre, W. Mains Rd., Edinburgh 9.]

Oestradiol dipropionate was injected into 2 groups of 12 immature pullets, 11 weeks old; one group had a daily dose of 1 mg. and the other rising daily doses up to 2 mg. The birds were killed after 12 days and Mn was estimated in blood and tissues. Five non-laying and 7 laying birds were controls for Mn content of blood.

No Mn was detected in the plasma of control non-laying pullets; in that of laying pullets there was 6.35 μg . per 100 ml. and in that of treated birds 34.9 μg . for the rising dose and 13.8 μg . for

N.A. and R., October 1955

the steady dose. Mn in the liver of the treated birds was about 78 μg ., the value lying between those for non-layers, 58.4 μg ., and for layers, 89.3 μg .

It is suggested that the liver acts as a labile reserve of Mn for egg production.—J. S. Thomson.

HALVERSON, A. W., HENDRICK, C. M. and OLSON, O. E. Observations on the protective effect of linseed oil meal and some extracts against chronic selenium poisoning in rats. *J. Nutrition*, 1955, 56, 51-60. [S. Dakota State Coll., College Station.]

Studies were made on groups of rats weighing 70 to 80 g., given diets all of which contained salts 2, animal-protein factor 0.1, dried brewers' yeast 2 and lard 3 per cent.; the remaining 92.9 per cent. consisted of maize, seleniferous maize and purified casein alone or with linseed meal or its fractions. The seleniferous maize was used in amount necessary to give the desired level of Se and sound maize was then used to complete the diet. Vitamins A and D were

supplied weekly. The animals were weighed twice weekly; the livers were examined for gross damage and weighed at the end of each experiment.

The protective effect of the linseed meal against Se poisoning was evident under several different conditions. The inclusion of 6 or 12 per cent. casein in the diets did not alter or mask the protective effect of the meal; meals prepared by several different methods were all found to be active. The protective principle was effective against inorganic Se as well as against the form which occurs in maize.

The protective principle was extracted from linseed meal with hot 50 per cent. aqueous alcohol. It was soluble in water and was not precipitated from solution by an excess of lead; the ash of active extract was not protective.—G. F. Garton.

ACID BASE EQUILIBRIUM

5374

KANTER, G. S. Heat and excretion in man. *J. Appl. Physiol.*, 1955, 7, 533-536. [Dept. Physiol., Albany Med. Coll., N.Y.]

The subjects, 15 male students, were exposed to temperatures of 120° to 130° F. in a hot room at low humidity, 10 to 20 per cent. Urine was collected and the subjects were weighed hourly. No water was given.

Most subjects tolerated only 4 hr. at 125° F. before fatigue, dizziness and thirst "destroyed their morale". They lost about 0.6 per cent. of their bodyweight hourly. The urine output was low and excretion of Na and Cl fell; that of K tended to increase. Bicarbonate disappeared from the urine after about 2 hr. and acidosis occurred.

The pH of the urine fell steadily and phosphate excretion rose. The arterial blood showed the existence of true acidosis, but this was not due to hypoventilation, because the CO₂ content fell slightly. The acidosis was therefore of metabolic origin.—D. Duncan.

5375

BIANCA, W. The effect of thermal stress on the acid-base balance of the Ayrshire calf. *J. Agric. Sci.*, 1955, 45, 428-430. [Hannah Dairy Res. Inst., Kirkhill, Ayr.]

Two Ayrshire calves 4 months old were kept in a hot room at 35° C. and 34 mg. per litre humidity

for from 2½ to 4½ hr. until rectal temperature reached 42° C. Venous blood samples were drawn and urine was collected before exposure and just before it ended. Respiration rate increased from about 45 to about 230 respirations per min. Plasma CO₂ combining capacity and CO₂ tension were significantly reduced. Lactic acid concentration in the blood and pH of the urine were significantly increased. The slight tendency of the pH of the plasma to rise was not significant.—T. D. Bell.

HOLLIDAY, M. A. (with LUKENBILL, A. and HANCOCK, C.) Acute metabolic alkalosis: its effect on potassium and acid excretion. *J. Clin. Invest.*, 1955, 34, 428-433. [Dept. Paediat., Indiana Univ. Med. Centre, Indianapolis.]

In groups of rats on an electrolyte-free diet chloride deficiency and alkalosis were produced by peritoneal dialysis. In 3 groups bicarbonate and in 1 group nitrate replaced chloride. In one of the bicarbonate replacement groups a load of NaHCO₃, and in another a load of NaH₂PO₄, was supplied intraperitoneally and by mouth. Compared with controls, all animals with alkalosis excreted large amounts of K with reduction of cell K and gain of cell Na as a result. Ingestion of Na accentuated these effects. The effects of alkalosis on excretion of ammonia and titratable acid were variable.

CASTILLON DU PERRON, M., JOLIET, J. F. and ANDRIVET, S. Sur l'élimination de l'eau pulmonaire au cours de l'effort. [Elimination of water through the lungs during work.] *C.R. Acad. Sci.*, 1955, **240**, 1925-1926.

The apparatus already described (Abst. 724, Vol. 25) was used to measure moisture expired after exercise for from 3 to 4 min. during which oxygen was breathed. For 5 subjects the amounts per ml. oxygen consumed were 0.51, 0.59, 0.63, 0.54 and 0.49 mg.; for the same subjects at rest they were, respectively, 0.61, 0.64, 0.65, 0.63 and 0.61 mg. It is concluded that, over short periods of exercise, the amount of water eliminated is less than during rest, and that the results with this apparatus are equal in accuracy to those obtained with apparatus of the Benedict type.—D. Harvey.

MULFORD, D. J. Diet of adult female rats and relation to kidney lesions in choline deficient offspring. *Proc. Soc. Exp. Biol. Med.*, 1955, **88**, 177-178. [Dept. Biochem., Sch. Med., Univ. Kansas, Lawrence.]

Mother rats were given a basal diet low in choline or the same with additions, per g. food, of 1 mg. choline chloride, 0.06 μ g. vitamin B₁₂, or both. Their young when weaned were given the same basal diet for 7 days; they were then killed and their kidneys were examined. In the groups in order the numbers of young examined were, males, 33, 40, 29, 26 and females, 34, 33, 34, 33.

Of these the numbers showing haemorrhages are stated to be: males, 26, 29, 8, 4, females 21, 6, 0 and 1 [table gives 4, not 1, for the fourth group of females].

In comparison with vitamin B₁₂, choline had little effect in preventing haemorrhage in the kidneys, but what effect it had was greater among females than among males.—D. Harvey.

DIOGUARDI, N. Considerazioni intorno al metabolismo ossidativo del tessuto epatico. Ruolo di un sistema capace di liberare energia. [The oxidative mechanism of liver tissue. Role of a system capable of liberating energy.] *Acta vitaminol.*, 1955, 9, 9-13. [Int. Clin. Med. Gen., Univ. Milan.] French, English, German and Spanish summaries.

Respiration was studied in liver homogenates from fasted rats, either in Ringer saline alone or with the successive addition of metabolic substrates (Krebs's medium), coenzymes and hexokinase with adenosine triphosphate.

Each addition progressively increased the rate of oxygen consumption by the homogenates. Substitution of glucose-1-phosphate or glucose-6-phosphate for the substrates and coenzymes was not effective. Heart tissue behaved like liver. In kidney and brain tissue the additions of substrates and coenzymes increased oxygen consumption, but the further addition of hexokinase and adenosine triphosphate had little effect.

It is concluded that the availability of free energy, as well as the presence of substrates and coenzymes, limits the endogenous respiration of tissue homogenates.—D. Duncan.

KHESIN, R. B. Obmen belkov v vazlichnykh strukturnykh elementakh tziotoplazmy kletok pecheni belykh kryss. [Protein metabolism in the different structural elements of the cytoplasm of rat liver cells.] *Biokhimiya*, 1954, 19, 407-413. [Inst. Biol. Med. Khim., Akad. Med. Nauk SSSR, Moscow.]

The rate of inclusion of labelled amino-acids into the protein of different structural entities in the liver cell was investigated in male white rats weighing 200 to 350 g. The animals were injected subcutaneously with methionine-³⁵S and tyrosine-¹⁴C and killed after varying intervals. Liver homogenates were separated into fractions corresponding with the cell components, and rates of uptake of the labelled substances by these components were then measured.

The rate of inclusion into the microsomes was greater than into the centrifugate or large granules. The rate into the latter was considerably slower than that into serum albumin, which is localised in corresponding ultracellular structures. The large granules consist of 2 components, the mitochondria with a slow rate of uptake and lighter granules with a much faster rate. When protein formation is rapid, the rate of amino-acid uptake by these large granules exceeds even that of the microsomes. Ribonucleic acid is almost absent from the mitochondria and its rate of P uptake runs parallel to the amino-acid uptake of the cell structures of which it is a component. The results are compared with those of studies of the exocrine cells of the pancreas.—D. W. Taylor.

ROGNONE, L., SPOSITO, M., RUSSO-CALA, S. and URBANI, E. Il comportamento di alcuni

sistemi interessati nella sintesi delle proteine (dipeptidasi-RNA) nel danno epatico provocato nel ratto dalla somministrazione di tetracoloro di carbonio. [Behaviour of some systems involved in protein synthesis (dipeptidases, RNA) in liver damage produced in the rat by carbon tetrachloride.] *Arch. ital. Malat. Appar. diger.*, 1955, 21, 87-123. [Ist. Anat. Comp., Univ. Rome.]

In the livers of rats poisoned with CCl_4 the total protein content and the dipeptidase activity did not differ significantly from those in normal controls. Ribonucleic acid was increased, and the Feulgen reaction showed considerable nuclear changes. The mode of action of CCl_4 is discussed. D. Duncan.

5393

NICOLAIDES, N., REISS, O. K. and LANGDON, R. G. Studies on the *in vitro* lipid metabolism of the human skin. 1. Biosyntheses in scalp skin. *J. Amer. Chem. Soc.*, 1955, 77, 1535-1538. [Dept. Med., Univ. Chicago, Ill.]

Normal skin was obtained at operation from the scalp of a woman aged 53 and slices about 0.5 mm. thick were prepared and incubated for 6 hr. with glucose and acetate- $1\text{-}^{14}\text{C}$ in Krebs Ringer phosphate buffer. The lipid constituents were then isolated and separated.

Of the total ^{14}C available, 12.2 per cent. was incorporated into the total skin lipids, 3 to 6 times as much as was incorporated by rat liver slices under identical conditions. Of the total ^{14}C activity in the lipids, free fatty acids contained 3.9, esterified acids 47.8, sterols 2.6 and squalene 39.6 per cent. On a weight basis much more ^{14}C was incorporated into esterified than into free fatty acids.

The specific activity of squalene was ten times that of sterols. Of the minor components the wax alcohols appeared to contain some radioactivity.

The results do not support the view of Popják (Abst. 3444, Vol. 24), who considered that squalene is not a precursor of cholesterol.—D. Duncan.

5394

POPJÁK, G. and TIETZ, A. Biosynthesis of fatty acids in cell-free preparations. 2. Synthesis of fatty acids from acetate by a soluble enzyme system prepared from rat mammary gland.

TIETZ, A. and POPJÁK, G. 3. Coenzyme A dependent reactions in a soluble enzyme system of mammary gland. *Biochem. J.*, 1955, 60, 147-155; 155-165. [Nat. Inst. Med. Res., Mill Hill, London, N.W.7.]

For part 1 see Abst. 3448, Vol. 24.

2. A soluble enzyme system prepared from buffered homogenates of the mammary gland of lactating rats was incubated in the presence of

^{14}C -carboxyl-labelled acetate and the effect of several substances on fatty acid synthesis was investigated.

Fatty acid synthesis in aerobic systems required the presence of adenosine phosphates. Stimulation of synthesis occurred when oxaloacetate or α -oxoglutarate was added; to a smaller extent succinate also promoted synthesis. The addition of malonate and α -oxoglutarate together brought about a considerable increase in the amount of ^{14}C -acetate incorporated into fatty acids.

Aerobic incubation caused inhibition of fatty acid synthesis only in the presence of oxaloacetate; no inhibition was apparent when α -oxoglutarate and malonate were added together.

Fatty acid synthesis was almost inhibited by HgCl_2 and arsenate; cyanide and 2:4 dinitrophenol caused some inhibition, azide and fluoride had no effect.

3. The soluble enzyme preparations described above contained about 50 μg . coenzyme A per ml. That coenzyme A activated acetate and other α -fatty acids was inferred from the formation of hydroxamic acids by reaction with hydroxylamine. The enzyme preparations contained "endogenous" substrates which gave rise to acetyl-coenzyme A and higher acyl-coenzyme A. α -Oxoglutarate and malonate had no effect on the formation of acetyl-coenzyme A. Inhibition of fatty acid synthesis by HgCl_2 was shown to be due to blocking of the formation of acetyl-coenzyme A.

When the enzyme preparation was treated with Dowex-1 ion-exchange resin it lost its ability to effect synthesis of fatty acids from acetate: the resin removed coenzyme A and diphosphopyridine nucleotide from the system, and restoration of synthetic activity was brought about when these coenzymes were re-introduced or when a boiled enzyme preparation was added.—G. A. Garton.

5395

PERRY, W. F. and BOWEN, H. F. Incorporation of acetate into fatty acid by liver slices of adrenalectomized rats. *Amer. J. Physiol.*, 1955, 180, 21-22. [Dept. Physiol. Med. Res., Univ. Manitoba, Winnipeg.]

Liver slices were obtained from adrenalectomized rats which had been fasted for 18 to 20 hr. or fed to appetite on Fox Chow diet, or pair-fed on the same diet, and from a normal rat as control for each adrenalectomized animal. The slices were incubated for 3 hr. at 37°C . in Krebs Ringer bicarbonate buffer containing $2\text{-}^{14}\text{C}$ -sodium acetate, after which the fatty acids were isolated and ^{14}C activity was estimated.

Compared with liver slices from similarly fed control rats, the slices from the adrenalectomized animals incorporated less acetate into fatty acids under all the conditions tested.—G. A. Garton.

5396

PERRY, W. F. and BOWEN, H. F. The effect of growth hormone on lipogenesis in intact and adrenalectomized rats. *Endocrinology*, 1955, **56**, 579-583. [Dept. Physiol., Univ. Manitoba, Winnipeg.]

Liver slices were prepared from normal rats, intact rats given growth hormone by injection, adrenalectomized rats and adrenalectomized rats given growth hormone. The slices were incubated with Na acetate-2- 14 C in Krebs Ringer bicarbonate buffer at 37° C. for 3 hr.; fatty acids were then isolated and tested for radio-activity.

Fatty acid synthesis in liver slices was inhibited by growth hormone given to both intact and adrenalectomized animals; in the latter the low incorporation of acetate was even further depressed.

G. A. Garton.

5397

GEYER, R. P., BOWIE, E. J., GONGAWARE, M. S. and RYAN, M. A. Studies on the metabolic interplay of fatty acids, succinate and electrolytes. *Arch. Biochem. Biophys.*, 1955, **55**, 104-113. [Harvard Sch. Pub. Health, Dept. Nutrit., Boston, Mass.]

Slices of heart, liver, kidney and spleen from normal rats were incubated with octanoate-1- 14 C in a medium containing 70 millimoles of K⁺ or Li⁺ per litre and in the presence or absence of succinate. The radio-activity of respired CO₂ and of acetate-carboxyl-C were studied. Similar experiments, with liver slices, were made with pentanoate-1- 14 C or palmitate-1- 14 C as substrate.

The formation of 14 CO₂ from labelled octanoate was decreased in the presence of succinate in heart and kidney. The effect of succinate on octanoate metabolism in liver slices, but not in kidney slices, was conditioned by the K⁺ concentration.

In further experiments, the formation of 14 CO₂ from octanoate-1- 14 C or succinate-2- 14 C by slices of liver, kidney, heart and spleen was studied. Succinate or octanoate alone was readily metabolised to 14 CO₂, except in the spleen, in which succinate was not readily broken down to CO₂.

The results are discussed in relation to the tricarboxylic acid cycle.—G. A. Garton.

5398

ARTOM, C. Effect of choline administration on the oxidation of fatty acids by extrahepatic tissues. *J. Biol. Chem.*, 1955, **213**, 681-687. [Dept. Biochem., Bowman Gray Sch. Med., Wake Forest Coll., Winston-Salem, N.C.]

Homogenates of liver, kidney, heart, brain and testis were prepared from young male rats which had been kept on low-protein diets. The homogenates were incubated in air in the presence of an emulsion of palmitate-1- 14 C and the radio-

activity of the respired CO₂ was measured. Some animals were given choline either by injection or by mouth shortly before being killed.

The administration of choline increased production of 14 CO₂ from palmitate in liver, kidney and heart homogenates; the same effect was produced occasionally with brain tissue, but not with testis.

G. A. Garton.

5399

KATZ, J. and CHAIKOFF, I. L. The metabolism of propionate by rat liver slices and the formation of isosuccinic acid. *J. Amer. Chem. Soc.*, 1955, **77**, 2659-2660. [Dept. Physiol., Sch. Med., Univ. California, Berkeley.]

The metabolic patterns of lactate in rat liver slices, studied with 14 C, resembled those of acetate, but from propionate much less 14 C was incorporated into fatty acids and ketone bodies and more into glucose and especially into succinate. Malonate reduced the production of 14 CO₂ from propionate-1- 14 C, but enhanced that from lactate-1- 14 C. Labelled succinate accumulated from propionate, but not from lactate. In paper chromatograms the "succinate" spot contained also isosuccinic acid up to a third of the total.

The results are consistent with the carboxylation of propionate to succinate by rat liver, and apparently there are enzyme systems which can add CO₂ to the β - and α -carbons of propionate, yielding, respectively, succinate and isosuccinate.

D. Duncan.

5400

RUDNEY, H. The synthesis of β , β -dimethylacrylic acid in rat liver homogenates. *J. Amer. Chem. Soc.*, 1955, **77**, 1698-1699. [Dept. Biochem., W. Reserve Univ. Med. Sch., Cleveland, Ohio.]

The results of isolation and degradation of β , β -dimethylacrylic acid formed from acetate-1- 14 C in rat liver homogenates are in agreement with the hypothesis of Bloch *et al.* (*J. Amer. Chem. Soc.*, 1954, **76**, 3859) that the substance is a precursor of cholesterol.—D. Duncan.

5401

FORSSBERG, A. and LARSSON, S. The "feeding centre" of the hypothalamic region of the rat brain. *Experientia*, 1955, **11**, 158-160. [Inst. Radiophys., Karolinska Sjukhuset, Stockholm.] German summary.

Rats received intraperitoneally 200 μ C. of Na₂H³²PO₄ after they had been fed or fasted for 24 hr., and were killed 15 to 60 min. later. Other rats received the isotope before the fast. Radioactivity was measured in samples of frozen hypothalamus, cerebrum, blood, liver and muscle.

Concentration of 32 P in the muscles, cerebrum and blood was similar in fed and fasted rats. The part of the hypothalamus containing the feeding

centre took up more activity in hungry than in fed rats and the adjacent areas less. The amounts of total P did not differ. The concentrations of hydrolysable end-groups of adenosine triphosphate plus creatine phosphate were similar in distribution to ^{32}P .

It is suggested that hunger may be regulated through a mechanism involving the reactions suggested by Nachmansohn (*J. Cell. Comp. Physiol.*, 1952, 39, 137). The analyses also indicate the existence of biochemical differences between closely adjacent areas of brain tissue.—D. Duncan.

GROWTH AND METABOLISM OF TUMOUR CELLS

5404

INFANTE MIRANDA, F. Las mucoproteínas del plasma en los estados cancerosos. [Plasma mucoproteins in cancer.] *Rev. clín. española*, 1955, 57, 81-87. [Clín. Med., Univ. Granada.] English, German and French summaries.

Plasma mucoproteins were estimated in 37 cancer patients, 19 others with different disorders and 10 healthy controls. The mean values for the 3 groups, in mg. per 100 ml., were 72, 4.8 and 3.66. The highest values were in tumours of the mucosae and organs and especially in female genital tumours. In the non-cancer patients high values occurred in cirrhosis, pulmonary tuberculosis and abscesses and Malta fever. The plasma mucoprotein may be of diagnostic value, especially in relation to the presence of metastases.—D. Duncan.

BUSCH, H. and GREENE, H. S. N. Studies on the metabolism of plasma proteins in tumor-bearing rats. *Yale J. Biol. Med.*, 1955, 27, 339-349. [Dept. Med., Sch. Med., Yale Univ., New Haven, Conn.]

Rats implanted with the Walker 256 carcinoma or the Jensen sarcoma were injected with glycine or lysine labelled with ^{14}C ; the amino acids were incorporated into tumour proteins to give specific activities of the same order of magnitude as those of other tissue proteins 1 to 6 hr. after injection. When rat plasma protein labelled with glycine or lysine was injected, the specific activity of tumour protein was considerably greater than that of other tissue proteins. The specific activity of the proteins of both microsomal and mitochondrial fractions separated from tumour cells was also considerably greater than that of the corresponding fractions from liver, kidney or lung. It was calculated that the daily turnover of plasma protein by the tumour was approximately equal to the weight of the tumour. C. Warner.

LLEWELLYN-JONES, D. Premature babies in the tropics. *J. Obstet. Gynecol. Brit. Empire*, 1955, **62**, 275-279. [Gen. Hosp., Kuala Lumpur.]

After 12 months' experience in a premature baby unit in Malaya it is suggested that the international standard of prematurity, a birthweight of 5½ lb. (2500 g.) or less, is unrealistic for that country. If an upper weight limit of 4 lb. 7 oz. (2000 g.) is adopted, the incidence of prematurity and mortality among those babies then approximates the U.K. and U.S. figures. It is concluded that each country and each race will have to decide upon its own standard of prematurity.

Simple management of premature babies, dictated by a shortage of nursing staff at the hospital, is described, and tables are given to show the mortality rates in different weight groups and among babies of different races.—F. E. Hytten.

TOMPKINS, W. T. and WIEHL, D. G. Epiphyseal maturation in the newborn as related to maternal nutritional status. *Amer. J. Obstet. Gynecol.*, 1954, **68**, 1366-1376 (with discussion 1376-1377). [Nutrit. Res. Clin., Pennsylvania Hosp. (Philadelphia Lying-in Hosp.).]

The babies studied were an unselected series of over 300 which weighed 5.5 lb. or more at birth and 3 of 39 weeks' gestation which weighed between 5 and 5.5 lb. The mothers had been registered at the Nutrition Research Clinic at Pennsylvania Hospital since the 16th week of pregnancy or earlier and were divided into 4 groups given no special supplement, or a polyvitamin concentrate, or a protein concentrate designed to provide 50 g. extra protein daily, or both. There was no serious deficiency in the diets, which contained on the average 76 g. protein daily and 860 mg. Ca. The stage of maturation of the epiphyseal centres of the knee and heel of each baby was estimated by X-ray photography within 5 days after birth and in about half of them a month later. Results are shown in tables and histograms.

Maturation of the epiphyseal centre at the distal end of the femur was well advanced in all babies at birth, but the centre at the proximal end of the

tibia was absent in 20 per cent. That in the os calcis was absent in 48 per cent., and it developed significantly later in white than in negro infants and in boys than in girls. There was no statistically significant effect of supplements on the os calcis centre, but the tibial centre was present in more infants from supplemented than from unsupplemented groups, though the difference was significant only in boys. There was no effect on the distal femoral centre.

Among the babies who had no os calcis centre at birth, about a third still lacked it a month later. The sex and race differences were much less, but girls were still slightly ahead of boys. When the tibial centre was well developed at birth it progressed less in the first month than when it was just beginning to develop. The same was true of the femoral centre; those largest at birth did not grow at all in the first month.

The presence of the tibial centre in the knee at birth was considered a more sensitive index of maturity than that of the os calcis or femur.

BOYD, E. Pictorial and graphic analysis of the body build of one boy. *Amer. J. Dis. Child.*, 1955, **89**, 332-340. [Child Res. Council, Denver, Colo.]

A longitudinal study of changes in body shape during growth on about 100 children from birth to 20 years, based on yearly photographs, anthropometrical measurements and X-ray photographs (see Abst. 3292, Vol. 13) should be completed within the next 5 years. This is a preliminary report on one subject to illustrate the methods. Changes in relative proportions with age are shown by the iconometric method of Wilmer and Seammon (*Human Biol.*, 1945, **17**, 314), i.e., by enlarging a series of whole-body photographs to constant height. For comparisons with other boys, anthropometric data are plotted in different ways against tentative smoothed percentile values for the group.—W. M. Deans.

5416

THOMSON, J. Weight and height of children aged four years. *Med. Officer*, 1955, **93**, 317-318. [Dept. Child Life, Univ. Edinburgh.]

The study was of 104 boys and 109 girls all born in the same maternity unit and aged 4 years \pm 7 days. Measurements were made of weight and of crown-heel and crown-rump lengths in supine

position. Mean values were for boys, 35.59 lb. and 40.55 and 24.24 in. and for girls, 34.48 lb. and 40.02 and 23.83 in. The means are greater than those reported in 1926 for Edinburgh children by Paton and Findlay (*Med. Res. Council Spec. Rep. No. 101*). Rather than that the comparison for an individual child should be made with values for standard tables it is suggested that regression equations should be used to predict weight from measured height.

For boys

$$y = 569.5 + 11.65 (x - 102.9)$$

and for girls

$$y = 551.85 + 12.6 (x - 101.665)$$

where y is weight in oz. and x is height in cm.

CHEESEMAN, E. A. and WALBY, A. L. The physique of Belfast school children. *Ulster Med. J.*, 1954, 23, Suppl. 3, pp. 63. [Dept. Social Med., Queen's Univ., Belfast.]

Belfast schoolchildren from 5 to 13 years old born on the first 7 days of each month, 12,700 in all (about 1 in 5), formed the sample and measurements of height, weight and intercrystal diameter were obtained for 11,425 of them, 5755 boys and 5670 girls, by a single team of workers during the year 1951-52.

The results are presented in tables and graphs, occupying about half the paper, for boys and girls separately, and in both metric and British units, with hints on their use. The principal tables give mean, S.E. of mean, S.D., median, first and ninth deciles and percentage coefficient of variation of height, weight and intercrystal diameter for each year of age. Similar particulars are given for weight and intercrystal diameter for height at 5-cm. intervals between 100 and 155 cm. There are also a number of distribution tables and graphs of dispersions. The results are compared with those obtained at routine school medical inspections in Belfast and with those of Daley ("Report on the Heights and Weights of School Pupils in the County of London in 1949", London County Council, 1950), and of Sutcliffe and Canham ("The Heights and Weights of Boys and Girls", John Murray, London, 1950) for England. The mean heights and weights of the Belfast children were consistently less than those of the London children and the differences increased with age, from under 1 cm. and 1 kg. at 5 years to about 3 cm. and 3 kg. at 13. Some of the weight difference may be due to differences in clothing.

Weight for a given height was also generally greater in the London children. Compared with the English children, the Belfast children, especially the boys, increased in height less steeply with age, and their heights and weights showed greater dispersion.—W. M. Deans.

5419

WOLFF, O. H. Obesity in childhood: a study of the birth weight, the height, and the onset of puberty. *Quart. J. Med.*, 1955, 24, 109-123. [Dept. Paediat., Univ. Birmingham.]

Literature is reviewed. The study concerns the first 100 obese children seen at a new obesity clinic, of which a dwarf and one who had had poliomyelitis were excluded. Birthweight was normal. Comparisons of height and weight are made with Engelbach's 1932 [presumably American] standards and Widdowson's 1947 data for English children of the professional class. The average obese child was 1.6 in. taller than the ordinary American, but only 0.3 in. taller than the English professional. When weight was reduced in greater or less degree after prescription of a 1000-Cal. diet with 50 to 60 g. protein the rate of gain in height was less, down to about 82 per cent. of Engelbach's standard, the greater the percentage loss of weight. If no weight was lost, gain in height was above standard. This is interpreted as meaning that the primary disturbance is not an abnormal growth-regulating mechanism but a disturbance of the regulation of appetite, resulting in excessive eating. Further, the limits of approximately 82 and 108 per cent. of standard are thought to indicate the limits within which in these children restriction of food, or excess of food, can affect growth in height.

Puberty occurred about 1 year in advance of average or 6 months in advance of tall children. Reduction of weight might be expected to delay the onset of puberty and so to give a still greater ultimate height of obese subjects since "in the normal child, growth ceases within four to five years of the onset of puberty", which is taken as at the average age of 12.9 years (Hogben *et al.*, *Brit. J. Soc. Med.*, 1948, 2, 29).—I. Leitch.

NEWMAN, R. W. and MUNRO, E. H. The relation of climate and body size in U.S. males. *Amer. J. Phys. Anthropol.*, 1955, 13, 1-17. [Quartermaster. Res. and Development Centre, Natick, Mass.]

A study of 15,000 young white men, measured on induction into the army, is reported. Mean annual and mean January and July temperatures and July noon "effective" temperature for 48 states were related to the mean weight: surface area (DuBois), weight, surface area and height of the men born in them. There was a significant

negative correlation between temperature and weight, surface area and weight per unit surface area, which was greatest for January temperature. This correlation cannot in general be attributed to difference in racial derivation of the state groups or, on a test of distribution of income per head in 1950, to difference in economic status. Since the effect of cold was greater than that of heat, adaptation for heat disposal by restricting mass relative to surface area cannot be regarded as causal. A combination of "expanded" appetite and muscular activity in colder regions is taken as the most likely explanation.—I. Leitch.

MØLLGAARD, H. Analyse des Wachstums mittels Differentialgleichungen der Partialprozesse des synthetischen Stoffwechsels. [Analysis of growth by differential equations of partial processes of synthetic metabolism.] *Ztschr. Tierernährung Futtermittelk.*, 1955, 10, 1-25. [Lab. Physiol., Landwirtschaftl. Versuchsstat., Copenhagen.]

Studies of growth are usually confined to recording liveweight gain and consumption of food units, or to metabolism experiments on retention of N, Ca and P. Since modern biology teaches that the body components are not fixed, but are constantly renewed, it is proposed that growth should be measured, starting from a fixed convenient weight and age at which composition of the carcass is known, and adding to that from the results of metabolism experiments to get composition at a later desired age and weight. Differential equations for the purpose are outlined.

This theory was tested with data for pigs, 7 sows and 6 barrows (castrated boars) for composition in terms of N, Ca and P at 60 days and (in the sow used as illustration) 8 balances between then and 175 days. Composition in terms of protein ($N \times 6.25$), Ca and P is shown to be represented by 3 straight lines. The rates of increase are therefore represented by hyperbolic functions of age and the effect of any change in diet is measured by the change in the constant of the equation, at least over the most important age interval 60 to 190 days.

Illustrative examples of the effect of interruption in the supply of pyridoxine and of the addition of antibiotics to a constant diet are discussed. In the last example aureomycin produced additional weight gain and an economy of feed consumption per unit gain. Detailed metabolism studies on 2 controls and 4 pigs with aureomycin showed that a little more fat was laid down per unit metabolisable energy by the aureomycin pigs and slightly less heat was lost. But the difference was not such as to explain the difference in weight gain or feed used. The deduction is "that every factor

that causes increased retention of water in the body will always give the appearance of improved utilisation, when utilisation is expressed as feed units per kg. growth."—I. Leitch.

SCHULTZE, M. O. Effects of malnutrition in early life on subsequent growth and reproduction of rats. *J. Nutrition*, 1955, 56, 25-33. [Dept. Agric. Biochem., Inst. Agric., Univ. Minnesota, St. Paul.]

Studies were made on the offspring of female rats during pregnancy and lactation rations which contained 8 or 16 per cent. of a mixture of essential amino-acids plus 5.1 per cent. ammonium citrate, or 12.2 per cent. of a mixture of 16 amino-acids. These rations (for the details see Abst. 4989, Vol. 25) were accessible to the young until they were 4 weeks of age and to some of the young male rats until they were about 20 weeks old; the animals were then transferred in groups of 4 or 5 to metabolism cages and were given, to appetite, a diet containing rolled oats 84, casein 6.5, salt mixture 3, wheat germ oil 2, maize oil 1, sucrose and a vitamin mixture, and DL-methionine 0.33 per cent. Weight increases were recorded for 6 to 12 weeks after the animals had reached the weight of 35 to 40 g.; females were mated at about 150 g.

The weight increase of the stunted young rats during the first 6 weeks of re-alimentation was about 80 per cent. of that attained by animals in which early growth had not been retarded. During the second 6 weeks of re-alimentation the growth of male rats was severely retarded; many reached a subnormal stationary weight and were permanently stunted. Male rats with early growth restricted for 20 weeks made an incomplete recovery during re-alimentation. The retardation of growth in the female rats did not affect their reproductive performance, and the survival of their young and their growth before weaning were normal.—G. F. Garton.

OLIVER, M. F. and BOYD, G. S. Plasma lipid and serum lipoprotein patterns during pregnancy and puerperium. *Chin. Sci.*, 1955, 14, 15-23. [Dept. Cardiol., Royal Infirmary, Edinburgh.]

The subjects were 12 normal primigravidae 18 to 31 years old, studied fortnightly from the ninth week until confinement, and several more blood samples were taken up to 20 weeks *post partum*.

The infants weighed at birth between 6 lb. 1 oz. and 8 lb. 12 oz., and the stage of gestation of all the samples was calculated back, the last one before delivery being taken as representative of the 39th week.

The mean plasma total cholesterol rose steadily from a mean of 187 ± 35 mg. per 100 ml. at the 9th to 282 ± 57 at the 31st week, and fell again from 283 ± 60 at the 33rd week to 239 ± 56 at confinement and 201 ± 45 at the 20th week *post partum*. Both free and ester fractions were affected, but the free : ester cholesterol ratio fell somewhat at the 39th week. Plasma phospholipins and the cholesterol : phospholipin ratio rose by about 25 per cent. between the 9th and the 31st week. The proportion of cholesterol carried on the β -lipoproteins rose also to the 32nd week. By the 20th week *post partum* all but one of the women had ceased lactation and had had at least one menstrual period, but none of the values had dropped to those in the first trimester.

The pattern of circulating lipids in the last trimester is similar to that seen in coronary sclerosis.—D. Duncan.

5425

HELLER, L. Stickstoffbilanzen in den letzten drei Schwangerschaftsmonaten. [Nitrogen balances in the last three months of pregnancy.] *Arch. Gynäkol.*, 1954-55, **185**, 566-572. [Frauenklin., Univ. Frankfurt a.M.]

The pregnant volunteers lived during the experiment under strictly controlled conditions and did light work in the laboratory. The diet was not standardised, but provided about 2850 Cal. daily. The main source of protein varied in a 4-day cycle of bread, vegetables, meat and fish. One subject was studied for 8 consecutive days and one for 4 days in the eighth month of pregnancy, 4 each for 4 days in the ninth month and 4 for 4 days in the tenth. Each balance period was preceded by 2 days of low-protein diet. The mean daily intake was 110 g. protein, providing 17 per cent. of the total energy.

The mean N retention in the 3 months studied was 5.03, 5.92 and 6.35 g. daily, representing a total of 483.9 g. [given as 473.9 in the summary], or 2900 g. protein. It is recognised that the last balances were made 3 weeks *ante partum*, so allowance should be made for the losses of N expected in the last days of pregnancy. The author concludes that to fulfil the demands of pregnancy at least 90 g. protein daily, and preferably 100 to 120 g., should be taken in the last 3 months, amounts which agree closely with the National Research Council's recommended allowance.—D. Duncan.

5426

NORDIN, B. E. C. and ROPER, A. Post-pregnancy osteoporosis. A syndrome? *Lancet*, 1955, **263**,

431-434. [Dept. Med., Postgrad. Med. Sch., London.]

Four young women developed backache and compression fractures of vertebrae during or soon after pregnancy. There was nothing to suggest inadequate intake of Ca or vitamin D and biochemical and X-ray investigations indicated that the disorder was not osteomalacia but osteoporosis. Increase of adrenocortical activity during pregnancy is suggested as a cause. Recovery was apparently spontaneous, though 2 of the subjects were treated with testosterone and oestrogens and one with methyl androstenediol.—W. M. Deans.

5427

HAFEZ, E. S. E. and KAMAL, M. A. M. Physiochemical investigation on placental fluids of buffalo. *Indian J. Vet. Sci.*, 1955, **25**, 39-45. [Dept. Animal Breeding, Fac. Agric., Fouda Univ., Giza, Egypt.]

The uteri were removed from 23 pregnant Egyptian buffaloes, representing 5 stages of the first 5 months of pregnancy. The diameter of the foetus was better than the weight as an indication of the stage of pregnancy. Sp. gr. of the amniotic fluid ranged from 1.004 to 1.009, that of allantoic fluid from 1.006 to 1.012, with a tendency to increase with the advance of pregnancy. There were only traces of reducing sugars and the presence of glycogen was doubtful in amniotic fluid, and in allantoic fluid there were small quantities of reducing sugars and no glycogen. Neither fluid contained ketone bodies, and creatinine was not detected by qualitative analysis in the amniotic fluid, but in allantoic fluid it was present in increasing amount as pregnancy advanced. There was little N in amniotic fluid. Allantoic fluid contained 58 mg. total N per 100 ml. with 2.25 mg. creatinine and 2.25 mg. amino-N in early pregnancy. These values increased significantly to 169, 44.19 and 15.38 mg. per 100 ml. at the latest stage of pregnancy examined.—T. D. Bell.

5428

WHIPPLE, G. H., HILL, R. B. (Jr.), TERRY, R., LUCAS, F. V. and YULE, O. L. The placenta and protein metabolism. Transfer studies using carbon¹⁴-labeled proteins in dogs. *J. Exp. Med.*, 1955, **101**, 617-626. [Dept. Pathol., Sch. Med. Dent., Univ. Rochester, N.Y.]

Three pregnant bitches, 2 at term and one at mid-pregnancy, were given ¹⁴C-labelled plasma intravenously and 2 more, one at term and the other at mid-pregnancy, were given ¹⁴C-labelled lysine by mouth. The pregnancies were terminated 2 to 4 days later and ¹⁴C was estimated in maternal and foetal tissues.

N.A. and R., October 1955

When the ^{14}C was given intravenously the maternal plasma contained about 10 times as much as the foetal plasma, but the concentrations in other tissues were similar in mother and foetus. When the ^{14}C was given by mouth, plasma and tissue levels were similar. The only notable deviation was in Hb; foetal Hb always contained considerably more ^{14}C than maternal. Compared with previous experiments it seems that "the pregnant dog metabolizes considerably more plasma protein per unit of time than does the normal dog", owing to an increased turnover of tissue protein and not to loss. Up to 1 per cent. of the dose of ^{14}C was transported across each placenta daily at term, much less at mid-term. There was a considerably greater daily transfer to each foetus after ^{14}C given by mouth than after intravenous ^{14}C [but there were only 3 and 4 foetuses present in the former and 7 and 11 foetuses in the latter and they were examined after different periods of time, so that comparison is difficult].

Neither plasma protein labelled with ^{131}I nor Evans Blue crossed the dog placenta and artificial raising of the level of plasma protein from 5.8 to 9.1 g. per cent. on the day of delivery did not cause a rise in foetal plasma protein.

The general conclusion is that the dog's placenta does not pass protein freely, but actively "accepts and possibly modifies" maternal circulating protein for foetal needs.—F. E. Hytten.

5429

NELSON, M. M. and EVANS, H. M. **Maintenance of pregnancy in absence of dietary protein with progesterone.** *Proc. Soc. Exp. Biol. Med.*, 1955, **88**, 444-446. [Inst. Exp. Biol., Univ. California, Berkeley.]

In a previous paper (Abst. 2444, Vol. 25) it was shown that, in the absence of dietary protein, pregnancy could be maintained in 70 per cent. of rats by daily injections of 4 mg. progesterone. To determine whether this was the optimum amount, daily amounts ranging from 1 to 8 mg. were tested. In the first series with rats killed at the 13th day of pregnancy, maintenance of pregnancy increased as the amount of progesterone rose to 6 mg. daily. In a second series in which the animals were killed at the 21st day of pregnancy, maintenance of pregnancy increased as the amount of progesterone rose to 4 mg. daily. At this level 70 per cent. of the animals showed live foetuses. Greater amounts did not prove to be more beneficial.—J. S. Thomson.

5430

CARTER, M. W., MATRONE, G. and SMART, W. W. G. (Jr.) **Effect of genistin on reproduction of the mouse.** *J. Nutrition*, 1955, **55**, 639-645.

Vol. 25, No. 4

[Animal Nutrit. Sect., Dept. Animal Indust., N. Carolina Agric. Exp. Stat., Raleigh.]

A diet containing 0.2 per cent. pure genistin or 0.08 per cent. in the form of soya bean meal caused the vagina to open significantly earlier in immature mice. The numbers of litters born were 59 and 77 per cent. and on control diet 82. Average numbers of young born to each female were 3.2, 4.5 and 4.9. The average number of young per litter and their average weight were not significantly different.—A. Hepburn.

5431

MAGNUSSON, G., BERGSTRÖM, I. and ODEBLAD, E. **Studies on the uptake of Fe^{59} in rat embryo, placenta, uterus and mammary gland.** *Acta radiol.*, 1955, **43**, 227-232. [Med. Clin., Serafimerlasarettet, Stockholm.]

Pregnant rats received by subcutaneous injection on the 20th day of gestation 200 μC . of Fe^{59} per kg. bodyweight. Embryos, placentas and mammary gland tissue removed from 1 to 7 days later were fixed and sectioned and distribution of the isotope was studied by autoradiography and with a scintillation counter.

From 1 to 5 days after injection the foetus contained more Fe^{59} than the placenta. There was much Fe^{59} in the mammary gland after 7 days, but it is not known whether this was related to the onset of lactation. In the foetus there was much Fe^{59} in blood and liver and a moderate amount in choroid plexus. The yolk sac placenta contained more than the allantoic placenta and none was found in maternal placenta and uterus. High accumulation was associated with endochondral ossification in cartilage, probably because of the presence of growing capillaries.—D. Duncan.

5433

KLEIBER, M., BLACK, A. L., BROWN, M. A., BAXTER, C. F., LUTOK, J. R. and STADTMAN, F. H. **Glucose as a precursor of milk constituents in the intact dairy cow.** *Biochem. biophys. Acta*, 1955, **17**, 252-260. [Dept. Animal Husbandry, Coll. Agric., Univ. California, Davis.] French and German summaries.

The cows were 2 Jerseys 6 years old, 4 and 3 months after calving. The first weighed 457 kg., gave 10 kg. milk daily, had a plasma volume of 20 litres by the Evans Blue method and an initial plasma glucose value of 60 mg. per 100 ml. Corresponding values for the second cow were 526 kg., 15 kg., 20 litres and 61 mg. The cows received by

intravenous injection glucose uniformly labelled with ^{14}C , at the rates of 6.27 and 2.76 μC . per kg. bodyweight in 1 g. glucose. The specific radio-activity of CO_2 and milk components is expressed by the quotient

$$\frac{\mu\text{C. per g. atom in C substance}}{\mu\text{C. injected per kg. bodyweight}} = \text{s.u.,}$$

i.e., the number of "standard units".

The activity of respired CO_2 reached a peak of about 9 s.u. 30 or 40 min. after the injection; the peak was lower than those after labelled acetate, propionate or butyrate (Absts. 778, Vol. 24; 2458, Vol. 25). In 3 hr. 1.6 times as much ^{14}C was recovered in milk as expired. In trial 1, 56 per cent. of the ^{14}C was recovered in milk in 2 days; of this 83 per cent. was in lactose, 11 per cent. in milk fat, 4 per cent. in casein and 2 per cent. in other substances, mainly albumin. In the other cow the recovery in milk in 2 days was 70 per cent., and its percentage distribution was in lactose 79, milk fat 13, casein 5, albumin 2 and citric acid 0.7. The highest specific activity in fat was lower than after acetate, but higher than after butyrate.

In 3 hr. after injection the specific activity of the plasma had declined to 1 per cent. of the initial value as calculated from plasma volume, blood sugar and injected dose.

About 4/5 of the lactose carbon came from plasma glucose or a pool in rapid exchange with plasma glucose, as did 1/5 of the C in citrate and 5 per cent. of the C in casein and milk fat.

EL RIDI, M. S., AZOUB, W. M. and HAY, A. A. Über die Wirkung von Squalen auf die Förderung der Laktation von Ratten bei Fütterung mit gereinigter squalenfreier Nahrung. [Effect of squalene on promotion of lactation in rats after feeding a purified squalene-free diet.] *Hoppe-Seyler's Ztschr.*, 1955, 299, 283-287. [Dept. Biochem., Kasr El Aini Fac. Med., Cairo.] English summary.

It was earlier shown (Abst. 783, Vol. 21) that an extract from fenugreek oil promoted lactation in female rats on a fat-free diet. The active fraction was rich in squalene.

Young female rats received when they weighed 40 to 50 g. a squalene-low diet containing, per cent., cane sugar 65, casein 20, lard (containing about 4 mg. squalene per 100 g.), 9, salt mixture 4 and

vitamin mixtures 2. On this diet they grew and bred as well as controls on stock diet, but lactation failed. In 19 rats given the experimental diet with the addition of 10 mg. squalene daily, lactation was normal. The reason for the beneficial effect of squalene is not understood.—D. Duncan.

RUPE, C. O. and FARMER, C. J. Amino acid studies in the transformation of proteins of the hen's egg to tissue proteins during incubation. *J. Biol. Chem.*, 1955, 213, 899-906. [Dept. Biochem., Northwestern Univ. Med. Sch., Chicago, Ill.]

Microbiological estimations were made of the amino-acid content after hydrolysis of the white, yolk and embryo of hen's eggs at intervals during 400 hours' incubation. Histidine and valine fell slightly, but the other amino-acids remained constant in total amount throughout incubation. During the first 250 hr. the yolk was the sole source of amino-acids for the embryo; thereafter much use was made of the white. The different amino-acids of the yolk were used to different extents, glycine most and tryptophan least; but the amino-acids in the white were used in the same ratio as they occurred.—C. Warner.

SZEPSENWOL, J., SHONTZ, M. E. and MASON, J. Nitrogen concentration in embryonic tissues of the chick throughout development. *Amer. J. Physiol.*, 1955, 180, 519-524. [Winship Clin. Sch. Med., Emory Univ., Emory University, Ga.]

Total N, N.P.N., peptides, amino-acids, ammonia and amide N were estimated daily from the eighth day of incubation until hatching, in smooth muscle of the alimentary tract, heart, skeletal muscle, liver, brain and chorio-allantoic membrane of chicken embryos. The embryos were from eggs

N.A. and R., October 1955

from different breeds, between which no chemical difference was found. Two series of embryos were used, one for estimation of total N and the second for the other components; 5 to 20 embryos were analysed in each series for each day of incubation.

Total N increased continuously in all the tissues except liver, in which, after an initial increase, it remained constant between the thirteenth and twenty-first days. The greatest increase in total N occurred in skeletal muscle. N.P.N. was between 6 and 12 per cent. of total N. N.P.N. increased simultaneously with total N except in the digestive tract, where it reached a peak on the sixteenth day of incubation and then decreased slightly, while total N continued to increase. Peptide and amino-acid N increased gradually throughout development in all organs except liver and digestive tract, where they remained constant. The increases which occurred in total N and N.P.N. and its 2 components, peptide and amino-acid, were not parallel. The amide and ammonia N in the tissues were low and showed no appreciable change throughout development.—G. F. Garton.

5439

SZEPSENWOL, J., MASON, J. and SHONTZ, M. E. **Phospholipids and nucleic acids in embryonic tissues of the chick.** *Amer. J. Physiol.*, 1955, **180**, 525-529. [Winship Clin., Sch. Med., Emory Univ., Emory University, Ga.]

The P of the lipid, deoxyribonucleic acid, ribonucleic acid and protein were estimated daily from the eighth day of incubation until hatching, in the heart, liver, digestive tract, skeletal muscle, brain and chorio-allantoic membrane of chicken embryos. There was no significant chemical difference among eggs from several breeds. One series of embryos was used for estimating lipid P and a second series for nucleic acid; 6 to 30 embryos were analysed for each day of incubation in each series.

On the eighth day of incubation lipid P was highest in the liver and lowest in chorio-allantoic membrane; on succeeding days it increased in all 6 tissues studied, the greatest increase occurring in brain. Before hatching, lipid P decreased slightly in all the tissues except in brain, where it continued to increase. No correlation was found between the degree of activity of the 3 muscle tissues and their phospholipin content. The P of deoxyribonucleic acid and protein showed no appreciable change in whole embryos between the third and eighth days of incubation, but ribonucleic acid P increased slightly. In embryos of 8 to 21 days, deoxyribonucleic acid P rose slightly in heart, digestive tract, skeletal muscle and liver, decreased slightly in brain and did not change in chorio-allantoic membrane. Ribonucleic acid P

increased in all the tissues except liver, where it decreased. No absolute parallel was found between the changes in protein and ribonucleic acid content of a tissue.—G. F. Garton.

The distribution of ^{32}P given to laying hens in the electrophoretic patterns of egg yolk proteins is shown in diagrams.—D. Duncan.

5441

SALEM, H. and REDA, H. **Calcium and phosphorus metabolism and egg shell formation in Egyptian birds.** *Poultry Sci.*, 1955, **34**, 197-205. [Fac. Agric., Univ. Cairo.]

Ten hens received a basal diet adequate for laying except for a low Ca content providing about 0.2 g. Ca daily; half received 1.5 g. and half 3 g. CaCO_3 daily and those with the higher intake had also 3 g. cod liver oil. Later 5 birds on the lower Ca intake received daily for 10 days 0.3 g. diethylstilboestrol.

Detailed results for representative birds are shown in tables. Birds in both groups absorbed about the same amount of Ca, less than 1 g. daily. The serum Ca on both laying and non-laying days was somewhat higher in the birds on the lower intake, and was significantly raised by diethylstilboestrol. The birds on the high Ca intake laid smaller eggs and retained Ca; those on the lower intake were just in positive balance. P retention was lower and so was serum P with the high-Ca diet. The hormone did not affect P metabolism.

SHOCK, N. W. and YIENGST, M. J. **Age changes in basal respiratory measurements and metabolism in males.** *J. Gerontol.*, 1955, **10**, 31-40. [Sect. Gerontol., Nat. Heart Inst., Nat. Insts. Health, Bethesda, Md.]

The subjects were 152 men aged from 41 to 90 years in an old people's home; all were up and about.

There was no evidence of systematic change with age in respiratory rate, ventilation volume, tidal volume or pulse rate. There was a progressive rise in the oxygen content of expired air and falls in the CO_2 content of expired air, CO_2 elimination, oxygen uptake and calculated heat production. The decrement in B.M.R. with age was significant.

The linear regression equation gives a value for the decline in B.M.R. with age which agrees closely with that obtained by Quénuille *et al.* (Commonwealth Agric. Bureaux Tech. Commun. No. 17, 1951).—D. Duncan.

GILLUM, H. L., MORGAN, A. F. and JEROME, D. W. (with VOTAW, M. H. and SNOWDON, M.)
Nutritional status of the aging. 4. Serum cholesterol and diet.

MORGAN, A. F., MURAI, M. and GILLUM, H. L. 6.
Serum protein, blood nonprotein nitrogen, uric acid and creatinine. *J. Nutrition*, 1955, 55, 449-468; 671-685. [California Agric. Exp. Stat., Univ. California, Berkeley.]

For other parts see Absts. 3986, 5576, 5649, Vol. 25.

4. Free and total cholesterol were estimated in the serum of normal subjects, 234 men and 296 women aged from 50 to over 80 years who were living in their own homes. Total cholesterol ranged from 106 to 720 mg. per 100 ml. blood; the mean for men was 241 ± 8 and for women 270 ± 8 . Free cholesterol was 27 to 28 per cent. of the total for all groups. The mean for 43 other men over 60 years of age who were living in a county home was 209 ± 12 mg. per cent. Women had significantly higher levels than men between ages 60 and 80. In both sexes there was a sharp decrease at 75 or 80 years. There was a downward trend in the levels of the men with each decade, but in the women aged 60 to 75 there was a sustained high level after a sharp decrease at 54 to 59.

There was a positive correlation between both cholesterol intake and fat intake and serum cholesterol in both sexes; the correlation was lower when fat was of animal origin only. There was slight positive correlation between protein intake and serum cholesterol. In women there was a striking parallel between serum ascorbic acid and serum cholesterol; this was not apparent in men. In men, but not in women, who were 20 per cent. or more underweight or overweight, serum cholesterol was low or high, respectively, as were fat and cholesterol intakes. No relation was found in any group between blood pressure and serum cholesterol.

The N.P.N. constituents of the blood were studied in 255 and serum protein values in 573 men and women over 50 years of age, as part of the study already described.

The average serum protein value was 6.47 ± 0.06 g. per cent. for the men and 6.44 ± 0.05 for the women, the range 5.2 to 7.4. No correlation with protein intake was found, nor was there any age or sex difference, but there was a small positive correlation with Hb. Blood N.P.N. was 38 ± 1.4 mg. per cent. for the men and 34 ± 1.2 for the women; after 70 years the difference was not significant. In the men, but not in the women, N.P.N. was positively correlated with protein intake. Blood uric acid was 3.24 ± 0.19 mg. per cent. for the men and 2.98 ± 0.18 for the women; after 70 years the differences were less and the values lower. There was no correlation with fat intake, but there was a small positive correlation with protein intake in the men only. The mean blood uric acid for 9 men and 14 women aged from 18 to 40 years was 2.53 and 2.33 mg. per cent., respectively. The mean blood creatinine values, which were unaffected by sex or age, were 1.53 ± 0.11 mg. per cent. for the men and 1.50 ± 0.08 for the women. There was no correlation with protein intake. In the 23 young adults studied the mean values were 1.27 ± 0.10 mg. per cent. for the men and 1.18 ± 0.07 for the women.

G. F. Garton.

ACKERMANN, P. G., BUEHLER, H. J., TORO, G. and KOUNTZ, W. B. **Serum cholesterol, phospholipid and lipoprotein levels in elderly male subjects. *Proc. Soc. Exp. Biol. Med.*, 1955, 88, 447-448. [St. Louis Chronic Hosp., Mo.]**

In connection with previous studies (Abst. 3195, Vol. 25), serum cholesterol, phospholipids and S₁ 12-20 lipoproteins were estimated in between 60 and 80 men aged from 53 to 94 years in St. Louis Chronic Hospital.

S₁ 12-20 lipoproteins declined slightly with age, and were significantly correlated with serum cholesterol ($r = +0.56$). Phospholipin values were linearly related to cholesterol values.—W. M. Deans.

5446

EIBER, H. B., GOLDBLOOM, A. A., DEUTSCHBERGER, O., CHAPMAN, I. and LOEWIE, W. R. **An outline of the newer methods of study of atherosclerosis, with emphasis on the 80-100 year group. *Geriatrics*, 1955, 10, 213-220. [Bird S. Coler Mem. Hosp., New York Med. Coll., Flower and Fifth Ave. Hosp., New York.]**

The methods were applied to chemistry and to lipoprotein and electrophoretic patterns of blood, to X-ray studies of aorta and to electrocardiograms, and pathological changes in retinal vessels, aorta and coronary arteries. The subjects numbered 650 in the age range 20 to 106 years. The tendencies were for total lipids, certain lipoprotein classes and the atherogenic index calculated from them, and the degrees of aortic calcification and dilatation

to rise until ages between 60 and 75 years and thereafter to fall, but the question of what occurs in the general metabolism in this threshold phase remains unanswered.—D. Harvey.

LYOYD, L. E. and McCAY, C. M. The utilization of nutrients by dogs of different ages. *J. Gerontol.*, 1955, 10, 182-187. [Cornell Univ., Ithaca, N.Y.]

Twelve female beagles were used, 4 showing signs of ageing, 9 to 12 years old, 4 young adults 2 years old and 4 pups 3 months old. All were fed in turn on dog meal alone or with the addition of lard or casein or both, or a protein- and mineral-deficient diet of cornflakes with or without lard to yield rations high, medium or low in protein and

high and low in fat. Digestibility data were obtained for dry matter, protein, fat and carbohydrate and balance data for N, Ca and P.

Old age had no effect on the digestibility of the dry matter of the ration, but young pups could not digest the protein of a low-protein ration so well as adults or old dogs, and the fat in high-fat rations was also less easily digested.

Average balance data over the entire period showed the mature and adult dogs to be in negative Ca balance, while the pups were in positive balance except for the period on the cornflake diet of low Ca content. P was retained on all diets; retention was much higher in the pups. N was stored on all the rations except cornflakes; retention again was highest in the pups.—J. S. Thomson.

EXPERIMENTAL STUDIES OF IMMUNITY AND MICRO-ORGANISMS

5448

RAMAKRISHNAN, S. P. Studies on *Plasmodium berghei* Vincke and Lips, 1948. 16. Effect of ketogenic diet on the course of blood-induced infection of rats. 17. Effect of different quantities of the same diet on the course of blood-induced infection in rats. 18. Effect of diet different in quality but adequate in quantity on the course of blood-induced infection in rats. 19. The course of blood-induced infection in pyridoxine or vitamin B₆ deficient rats. *Indian J. Malariol.*, 1954, 8, 85-88; 89-96; 97-105; 107-113. [Malaria Inst. India, Delhi.]

16. Of 10 rats, 8 weeks old, 5 received a standard diet and 5 a ketogenic diet containing, per cent., butter 93, salt mixture 1, glucose 5 and vitamin "B" complex 1. After a week all were inoculated with *Plasmodium berghei*. The rats on the ketogenic diet lost weight, and those on the standard diet gained it. Survival times are not recorded. The number of parasites observed daily and at the peak of infection was much less in the rats given the ketogenic diet.

17. In a previous study (Abst. 3500, Vol. 24; see also Abst. 996, Vol. 25) experimental starvation was extreme. In the present study 92 rats were fed on a standard diet; 27 were given what was deemed to be enough, and 41 were given half the amount. They were all inoculated with one million organisms of *Plasmodium berghei* after 2 or 4 weeks. Another 24 were given half the amount of diet without inoculation. Six separate experiments were made in which rats of different ages from 7 to 27 weeks were used, and in which progressively more suitable amounts of food were given. The number of animals that died was not significantly different in the fully-fed and half-starved groups,

but in the latter the number of parasites in the blood was less.

18. In similar experiments, rats were given *ad libitum* a vegetarian diet, a lacto-vegetarian diet or a mixed diet containing meat. A group having each diet was compared with a group having a standard diet. Inoculation took place after from 1 to 4 weeks. With a mixed diet containing a small amount of meat, the number of parasites in the blood was least, less even than with the standard diet. With a rice and peanut diet, the number was about the same as with the standard diet, but with all the other diets the numbers were greater and with a high-meat diet greatest of all.

19. In a similar experiment, of 10 rats from 6 to 7 weeks old and two 18 weeks old, 6 were given a diet deficient in vitamin B₆, 3 were given the same diet with 75 µg. pyridoxine hydrochloride per head daily, and 3 had a standard diet. The rats were maintained on the diets for 121 days before inoculation. The number of parasites was much less in the blood of the deprived animals and none of them died in the acute phase of infection, but all those in the other groups died.—E. M. Hume.

GYLLENBERG, H. and LAMPILA, M. A lactate-utilizing *Corynebacterium* from the rumen of cattle. *Maataloust. Aikakausk.*, 1955, **27**, 53-56. [Dept. Microbiol., Univ. Helsinki.] Finnish summary.

The bacterium was isolated from bovine rumen fluid by plating on peptone, yeast extract and lactate agar, at dilutions of 10⁻⁵ to 10⁻⁷. In pure culture, volatile acids were produced from lactate. The characters of this organism were similar in most respects to those recorded for *Corynebacterium enzymicum* (Bergey's Manual), which is regarded as of human origin. It is considered that this organism is derived from soil or hay, and that some corynebacteria are not so essentially of human origin as has been supposed.—J. C. Appleby.

5456

APPLEBY, J. C. The isolation and classification of proteolytic bacteria from the rumen of the sheep. *J. Gen. Microbiol.*, 1955, **12**, 526-533.

[Rowett Res. Inst., Bucksburn, Aberdeenshire.]

The basal medium consisted of 45 ml. 0.3 per cent. K₂HPO₄ plus 45 ml. solution containing, per cent., K₂HPO₄ 0.3, NaCl 0.6, MgSO₄ 0.06, and CaCl₂ 0.06, with 6 g. agar, 1 ml. resazurin solution and either 1.5 g. yeast extract or 90 ml. clarified rumen fluid from a sheep on a low-protein diet, all made up to 300 ml. with distilled water. Sometimes 1.5 g. peptone was added. When this solution was boiled and filtered, to 200 ml. were added 34 ml. of 6 per cent. sterilised casein solution, 13 ml. of sterile 6 per cent. Na₂CO₃ and 3.4 ml. of 3 per cent. cysteine hydrochloride. CO₂ was bubbled through to reduce the resazurin and bring the pH to from 6.8 to 7.4.

Two sheep received groundnut meal, flaked maize and hay, the third maize, oats, bran, linseed meal, white-fish meal and a little hay. Rumen samples were taken through fistulae and lightly centrifuged before serial dilutions were prepared and used as inocula for roll tube cultures in the basal medium. They were incubated at 38° C. for 4 or 5 days.

Total viable counts for all 3 sheep were about 10⁶ to 10⁷ per ml. rumen fluid. The majority of the proteolytic organisms isolated were facultatively anaerobic bacilli, and of 24 isolates of this genus, 19 were *Bacillus licheniformis* which existed in vegetative form in the rumen. Spores of this organism were present in large numbers in the hay. Other proteolytic organisms included 4 cultures of *Clostridium sporogenes*, 5 Gram-negative rods, including species of *Proteus* and probably *Flavobacterium arborescens*, one species of *Corynebacterium* and 6 strains of micrococci. The proportion of proteolytic bacteria in the rumen is estimated as, at most, 1 per cent.—D. Duncan.

5457

GARTON, G. A. and OXFORD, A. E. The nature of bacterial lipids in the rumen of hay-fed sheep. *J. Sci. Food Agric.*, 1955, **6**, 142-148. [Rowett Res. Inst., Bucksburn, Aberdeenshire.]

Two wether sheep with rumen fistulae were fed on meadow hay, with access to water and a mineral lick. Samples of rumen contents were taken every second day and centrifuged to give a fraction consisting mainly of bacteria. The samples were combined and eventually dried in a vacuum spin freeze drier, and gave 110 g. dry substance, 0.5 to 1 g. being obtained from 1 litre of rumen contents. Lipids were extracted with ethanol and ether and amounted to 16.8 per cent. of the dry matter.

The fractionation of the lipids yielded, per cent., steam-volatile lower fatty acids 6.5, steam volatile neutral solid a trace, acetone-insoluble phospholipins 20.8, acetone-soluble neutral fat 20.2,

unsaponifiable 5.4, and water-soluble salts of acetic, propionic and butyric acids 47.1. No conjugatable dienoic or trienoic fatty acid, characteristic of grass fats, was found, and no cholesterol, the presence of which would have indicated cellular material of host origin such as desquamated rumen epithelium. The lipids were therefore derived mostly from bacteria, especially the species found free from plant fibres, such as saccharolytic forms.

The neutral fat contained fatty acids of high mean molecular weight, 312.0. The phospholipins had an N : P ratio of 1.6, indicating a mixture of mono- and di-aminophosphatides. No linoleic or linolenic acid was detected. The unsaponifiable matter contained a substance of approximate empirical formula $C_{27}H_{48}O_2$, but not identical with cholesterol monohydrate. Xanthophylls were present.—D. Duncan.

MISCELLANEOUS FEEDING EXPERIMENTS

5458

SPEERLING, G., LOVELACE, F., BARNES, L. L., SMITH, C. A. H., SAXTON, J. A. (Jr.) and MCCAY, C. M. **Effect of long time feeding of whole milk diets to white rats.** *J. Nutrition*, 1955, **55**, 399-414. [Dept. Animal Husb., Cornell Univ., Ithaca, N.Y.]

Six groups, each of 60 rats, were used to study the effect of 6 different diets on growth and life span, intake of food and fluids, reproduction and composition of the young, pathology, X-ray photographs of soft tissues, decay of teeth at the time of death, and bone density and Ca content. Twenty rats in each group were males, 20 were mated females and 20 were unmated females. The diets for 4 of the groups consisted mainly of whole fresh milk supplemented with traces of Mn, Fe, I, Cu and cod liver oil; one group received the milk alone, the second received milk with 10 per cent. sucrose dissolved in it, the third received the milk and had free access to dry sucrose and the fourth had similar access to a 10 per cent. solution of sucrose in water. The fifth group was given a mixed stock diet supplemented with 10 per cent. of its weight of cooked whole dried egg; the sixth received the stock diet alone. The animals were given the diets from weaning until they died.

The rats given milk containing dissolved sucrose were overweight throughout life; males failed to attain a normal life span and females failed in reproduction. Those given milk or milk containing dissolved sucrose had no decayed teeth at death, but those drinking milk with free access to sucrose either in solution or dry had much dental decay; the dry sucrose group suffered most from decayed molars. All the animals on milk diets had the densest bones in old age. The life span was not shortened by the consumption of 10 per cent. of whole egg in the diet; the life span of males was substantially increased thereby. Comparable animals consumed equal amounts of sucrose throughout life; females consumed more energy and more fluids per unit bodyweight than males.

The energy consumption remained fairly constant throughout life. Among the rats given milk diets about 20 per cent. had hair balls in the stomach; this was not modified by administration of ground cellulose. Mated females had more abscesses of the reproductive organs than virgin females. Among ageing rats there was a high incidence of diseases of the middle ear and lungs, but this could not be attributed to diet.—G. F. Garton.

5459

CLARK, H. E., HARRISON, D. L., SOULE, R. P. (Jr.) and RICHARDSON, D. **The nutritive value of proteins of muscle from hogs fed diets supplemented with aureomycin or terramycin hydrochloride.** *J. Nutrition*, 1955, **56**, 61-66. [Dept. Foods Nutrit., Kansas State Coll., Manhattan.]

Ten weanling pigs were given a ration of maize, soya bean meal, tankage, alfalfa meal, a mineral mixture and vitamin D; initially the diet provided 13 per cent. protein, during the growing period 15 per cent. and later 12 per cent. Ten similar pigs received the same diet plus 10 mg. aureomycin hydrochloride per lb. of basal ration and another 10 the diet plus 10 mg. terramycin hydrochloride per lb. Diets containing pork from these pigs were given to appetite to weanling rats for 4 weeks; N balances were measured during the last 7 days of the test and increments in liver N during the 4 weeks were estimated. In all diets pork provided 1.6 per cent. N; other constituents were Crisco 20, roughage 2, Richardson and Hogan salt mixture 5 and vitamin D oil 5, with dextrin to 100.

The presence of aureomycin and terramycin in the pork did not stimulate the growth of the rats, but N balance, expressed in terms of surface area, was significantly higher ($P < 0.05$) when pork from pigs on the basal ration was given to the rats than when pork from pigs given either of the antibiotics was given. The nutritive value of the pork proteins for the growing rat was similar to that of beef.—G. F. Garton.

- COHN, C., SHRAGO, E. and JOSEPH, D. **Effect of food administration on weight gains and body composition of normal and adrenalectomized rats.** *Amer. J. Physiol.*, 1955, **180**, 503-507. [Dept. Biochem., Med. Res. Inst., Michael Reese Hosp., Chicago, Ill.]

Male rats were given either a solid diet to appetite or a liquid diet by stomach tube twice daily. The diet consisted of salt 20, casein hydrolysate 95, lactalbumin hydrolysate 10, liver powder 10, methionine 2, 2-methylnaphthoquinone 50, sucrose 110, dextrin 105, maize starch 110, Mazola oil 100 g., cod liver oil 5, wheat germ oil 5, and vitamin B syrup 30 ml.; for the solid diet 310 ml. 5 per cent. agar and 320 ml. water were added to the basal diet, for the liquid diet 30 g. cellulose flour and water to make 1000 ml. After a week on the diets one-third of the animals in each group were adrenalectomized, another third had a sham operation and the rest were killed and their body composition was estimated. The diets were continued for another 14 days, after which all the animals were killed and tissues were analysed for fat; total body N was also estimated.

The animals which were adrenalectomized and tube-fed were similar in body composition to tube-fed control animals. Adrenalectomized rats fed to appetite lost body fat and gained less weight than control animals fed to appetite. Tube-fed control animals contained more body fat than normal animals fed to appetite, although the diet was the same and weight gains were similar.—G. F. Garton.

- VARTAINEN, I. and PAASONEN, M. **Selection of casein, gelatin and keratin in alloxan diabetes. Selection of proteins in alloxan diabetes. Selection of potassium and magnesium in alloxan diabetes.**

Influence of tyrosine on food selection in alloxan diabetes. *Ann. Med. int. Fenn.*, 1954, **43**, 324-328; 329-337; 338-340; 341-345. [2. *Med. Clin., Univ. Helsinki.*]

Rats caged individually were offered casein, gelatine, keratin, olive oil, sucrose and tap water and had access to mineral and vitamin supplements. After their dietary selection had become stabilised the rats were made diabetic by subcutaneous injections of alloxan over a period of from 1 to 32 days. Severe diabetes developed on the average in 17 days and the energy intake of the rats increased, the increase being only in protein and in the form of casein. The intake of fat and sucrose remained the same and that of keratin and gelatine was very low in both preliminary and diabetic periods.

The study of protein selection was continued with groups of normal and diabetic rats offered combinations of protein foods including casein, meat powder, dried egg yolk, dried fish, milk powder, fat-free egg yolk and egg yolk oil, and semolina. With a simple choice of 6 proteins, casein and egg yolk were most favoured by diabetic rats, whose energy intake per kg. bodyweight was 348 Cal. while that of healthy, non-diabetic rats was 269. The diabetic rats derived 40 per cent. of their energy from protein and the non-diabetic rats 13 per cent. The amino-acid content of the food patterns chosen by diabetic and non-diabetic rats was calculated. The intake of individual amino-acids by diabetic rats was increased by from 3.4 times to 6.8 times. The greatest increase was for alanine and aspartic acid and the least for glycine and cystine.

In another test, solutions of 1 per cent. magnesium chloride and potassium chloride were offered in addition to proteins. Although the diabetic rats were already consuming larger amounts of Mg and K in the food they showed also a higher intake of the solutions than the non-diabetic rats. The same result was obtained in 3 series of tests lasting for up to 112 days.

N.A. and R., October 1955

Administration daily for 2 weeks of 1 g. tyrosine per kg. bodyweight by injection, and then of 5 g. per kg. by mouth, to 9 diabetic and 10 normal rats on self-selection diets of sucrose, casein, olive oil, water, vitamins and salts resulted in a lower intake of sucrose, which was more marked in the diabetic rats. Subcutaneous injection of tyrosine caused a transient rise in blood sugar.

SCHOTTLE, C. E., REBER, E. F., MORRILL, C. C. and LINK, R. P. **Experimental production of hyperkeratosis in rats and hamsters.** *Amer. J. Vet. Res.*, 1955, **16**, 183-188. [Dept. Vet. Physiol. Pharmacol., Coll. Vet. Med., Univ. Illinois, Urbana.]

Rats and hamsters were given synthetic rations with either a protein concentrate known to produce hyperkeratosis in cattle (Link and Reber, *North Amer. Vet.*, 1954, **35**, 274) or a commercial chlorinated naphthalene containing pentachloronaphthalene, which has a similar effect (Sikes, *Science*, 1952, **116**, 506).

In the rats both additions caused alopecia and limited growth and time of survival; with the chlorinated naphthalene the vitamin A content of liver was reduced. In the hamsters the protein concentrate caused no gross sign of hyperkeratosis and weight was affected less than in rats; its effect in reducing the vitamin A content of liver was greater than that of the chlorinated naphthalene. The rat is considered to be more susceptible than the hamster to the action of these substances in producing hyperkeratosis.—D. Harvey.

terracyclin or streptomycin on growth, reproduction and lactation of the rat. *J. Nutrition*, 1955, **55**, 481-492. [Dept. Animal Nutrit., Pennsylvania State Univ., University Park.]

Three groups, each of 10 male and 30 female rats, were given at weaning finely ground Rockland rat diet alone or supplemented with 0.04 per cent. terramycin hydrochloride or streptomycin sulphate. They were mated at 4 months of age and again one month after their young were weaned.

There was no significant difference in reproductive ability between the groups. Weight gains of the offspring of animals given terramycin and streptomycin during the third to the fourteenth days *post partum* were significantly increased over weight gains of young from dams given the control diet; from the fourteenth to the twenty-first day *post partum*, when mother's milk was supplemented with solid food, there was still a significantly greater weight gain of male and female young given antibiotics. The second litters confirmed these results.

There was no significant difference in the average food intake of dams on different diets during lactation. Thirty-seven per cent. of the streptomycin and 80 per cent. of the terramycin was excreted in the faeces. Neither antibiotic had any significant effect on the fat content of the liver.

ROINE, P., ETTALA, T., RAITTO, A. and VARTIOVAARA, U. **The mode of action of aureomycin in the guinea-pig.** *Brit. J. Nutrition*, 1955, **9**, 181-191. [Dept. Nutrit. Chem., Univ. Helsinki.]

Groups of guineapigs were given to appetite a diet of ground clover and timothy hay 20, oatmeal 32, rye meal 22.4, casein 12, margarine 3.2, salt mixture 1.6, dried brewer's yeast 4, wheat germ 4 and cod liver oil 0.2 per cent., with 25 mg. ascorbic acid daily. One group of 9 young guineapigs received 100 mg. aureomycin hydrochloride per kg. bodyweight. All the animals lost weight from the second day of experiment and died within 10 days. When the aureomycin diet was given to 6 adult guineapigs all lost an average of 23 g. daily from the first day and died in 7 to 15 days. When aureomycin was given by mouth to groups of 4 or 5 animals in quantities of 25, 50 and 100 mg. per kg. bodyweight mortality was similar. Loss of weight and death occurred when 1 mg. aureomycin daily was given by subcutaneous injection to 4 animals, but smaller quantities did not prove harmful to groups of 3 or 4 animals. A group of 5 guineapigs which received an average of 0.2 mg. aureomycin daily by mouth died in 7 days, but a similar group given the same quantity subcutaneously remained in good health. With a

purified diet instead of the basal diet, results were similar and all 4 animals died within 8 days.

Bacteriological studies revealed the presence in the caecum of increased numbers of *Listeria* flora, particularly *Listeria monocytogenes*, when aureomycin was given by mouth, and this is believed to be the cause of the toxicity. Often the toxic effects were prevented or cured by previous or simultaneous administration of penicillin or chloramphenicol.—G. F. Garton.

5472

RUSHTON, M. A. **Dental effects of dietary aureomycin.** *Brit. Dent. J.*, 1955, **98**, 313-317.

Female hamsters were fed from 1 to 9 months of age on 3 similar diets, one with 35 per cent. and 2 with 28 per cent. powdered full cream milk, one of the latter with 0.002 per cent. aureomycin hydrochloride added. From each group 6 animals were killed and serial coronal sections were prepared and measured.

In the aureomycin group the epithelium extended less deeply along the molar roots, the thickness of dentine of the lower incisors was greater and the maturation of enamel was more advanced than in the other groups, the differences being statistically significant. The antibiotic is concluded to have had a general nutritional effect and not to have acted merely as a bactericidal or bacteriostatic agent.—D. Harvey.

5473

MELNYKOWYCZ, J. and JOHANSSON, K. R. **Formation of amines by intestinal microorganisms and the influence of chlortetracycline.** *J. Exp. Med.*, 1955, **101**, 507-517. [Dept. Bacteriol., Univ. Minnesota, Minneapolis.]

Paper chromatography of faeces and mixed faecal cultures from rats on a diet of fox checkers revealed the presence of putrescine and several other amines. These were mostly suppressed when chlortetracycline was added to the diet, or to the culture medium. It is suggested that the growth-stimulating effect of antibiotics may be due to reduction of output of toxic substances in the intestinal tract.—W. M. Deans.

FRENCH, R. G., ZIGHERA, C. Y. and MAYER, J. **Production of hypothalamic obesity in mouse.** *Federation Proc.*, 1955, **14**, 433-434. *Proc.* [Dept. Nutrit., Harvard Sch. Pub. Health, Boston, Mass.]

5476

MAYER, J. and BARNETT, R. J. **Obesity following unilateral hypothalamic lesions in rats.** *Science*, 1955, **121**, 599-600. [Dept. Nutrit., Sch. Pub. Health, Harvard Univ., Boston, Mass.]

Lesions were produced electrically in the right side of the hypothalamus in 29 rats; 13 rats showed abnormally large appetites afterwards and 5 of them when killed weighed more than 350 g. In all these 5 the ventromedian nucleus was destroyed and parts of the periventricular, lateral and arcuate nuclei. The weight gains of rats with unilateral lesions were less than those of rats with bilateral lesions, a quarter of which weighed more than 500 g. 100 days after operation and another quarter more than 350 g.

It is suggested that in rats 2 centres, bilaterally arranged, normally prevent excessive eating, and the removal of one is about half as effective as the removal of both.—D. Duncan.

5477

MCCLURE, F. J. and FOLK, J. E. **Observations on the production of smooth-surface rat caries by diets containing skimmilk and whey powders.** *J. Nutrition*, 1955, **55**, 589-599. [Nat. Inst. Dent. Res., Nat. Inst. Health, Bethesda, Md.]

Seven synthetic diets were given to groups of weanling rats for periods of about 90 days. Three contained 35 per cent. skimmed milk powder; one of the powders was prepared by a freeze-drying process in which the temperature never exceeded 40° C., the second by a spray and the third by a roller process. The 4 other diets contained 25 per cent. whey powder with 10 per cent. casein to raise the protein content to about 13.5 per cent., the same as in the skimmed milk diets. One powder was spray- and another roller-dried; the third and fourth were these same powders after additional heat treatment (autoclaving). The incidence of caries, generally in lower buccal areas, was measured by the methods described in an earlier study (see Abst. 958, Vol. 24).

The results showed that the caries-producing effect of the diet was, in general, parallel with the degree of heating which the milk powder had undergone. Differences in sources of supply of the whey powders and in the findings for the groups with the autoclaved products, only one of which showed that that extra treatment increased the incidence, prevented the deduction that heat treatment in particular was the cause. The more general conclusion was that these results confirmed earlier findings with processed foodstuffs (see Abst. 2112, Vol. 23).—D. Harvey.

MUHLER, J. C. and SHAFER, W. G. **Experimental dental caries. 8. Effect of thyroid-testosterone**

N.A. and R., October 1955

administration on dental caries in rat. *Proc. Soc. Exp. Biol. Med.*, 1955, **88**, 191-193. [Dept. Chem., Univ. Indiana, Bloomington.]

Experiments with groups of weanling Sprague Dawley rats of both sexes, 225 in all, receiving a cariogenic maize diet and drinking water low in F, confirmed the authors' previous finding (Abst. 1048, Vol. 25) that dried thyroid added to the diet reduced the number of carious lesions and thiouracil increased it, and showed also that testosterone by intramuscular injection, though itself without effect, reinforced the effect of thyroid. It is suggested that the effect of the thyroid on the

teeth may be mediated through the salivary glands.

Analysis of the femurs showed that none of the treatments significantly affected F storage.

PATHAK, S. P. and SUWAL, P. N. Composition of liver fats of mature and embryo sharks (*Galeocerdo tigrinus*). *J. Amer. Oil Chem. Soc.*, 1955, **32**, 229-230. [Hindu Univ., Banaras, India.]

Fat was obtained from the liver of a mature female shark, *Galeocerdo tigrinus*, and from the pooled livers of 18 embryos of the same species. The mixed fatty acids of both specimens of fat were analysed by ester fractionation after preliminary resolution into groups of acids of differing unsaturation.

The total amounts of saturated fatty acids in the mature and embryonic liver fats were 43.3 and 39.1 per cent. : the palmitic acid content was about 25.0 per cent. in both. The unsaturated fatty

acids from the mature fat included 15.5 and 9.3 per cent. of the total as C_{20} and C_{22} acids, but C_{20} unsaturated acids accounted for only 4.0 per cent. of the total from the embryos and no C_{22} unsaturated acid was found.—G. A. Garton.

HEGSTED, D. M. World wide opportunities. *J. Amer. Dietetic Assoc.*, 1955, **31**, 236-242. [Dept. Nutrit., Harvard Sch. Pub. Health, Boston, Mass.]

The world-wide opportunities which are considered are those which are generally recognised as existing for the improvement of diets in areas which, by western standards, are regarded as underdeveloped. From his own work and that of colleagues in Peru the intakes in particular of Ca, protein and riboflavin have been found to be below recommended allowances. These recommendations are, for most nutrients, based on data collected elsewhere, and both the acceptability of such

standards and the wisdom of bringing intakes to the high levels they propose are questioned. Emphasis is laid on the lessons to be learned from field studies in these countries on the necessity for integrating agricultural and economic advances with nutritional needs.—D. Harvey.

FEEDING OF INFANTS AND CHILDREN

5493

CALAMARI, A. Problemas de alimentación del prematuro. [Problems of feeding the premature.] *Rev. española Pediat.*, 1955, 11, 177-183. [Inst. Provincial Niños, Arezzo.] French, English and German summaries.

In part this is a general discussion of the subject. At Arezzo 478 premature infants were studied, among whom mortality was 23.2 per cent.; among the 230 weighing less than 2000 g. it was 32.1 per cent. Infants fed on breast milk alone gained, on the average, 25-65 g. daily, and those fed on breast milk with 25 to 50 per cent. buttermilk added, 26-93 g.

Fresh human milk with a proportion of buttermilk is considered ideal for premature infants.

D. Duncan.

5494

GLEISS, J. and BÜSCHER, L. Beiträge zum Frühgeborenenproblem der Gegenwart. 7. Vergleichende Untersuchungen zur Ernährung der Frühgeborenen mit einer evaporierten 4/5-Milch, einer Frauenmilch mit Buttermilch-zusatz und einer mit unverdünnter, evaporierter Milch (Doppelmilch) angereicherten Frauenmilch. Zugleich ein Beitrag zur Fettoleranz des frühgeborenen Kindes. [The problem of the premature today. 7. Comparative studies of feeding premature infants on an evaporated 4/5 milk, breast milk with added buttermilk and breast milk enriched with undiluted evaporated milk (double milk). Also on the fat tolerance of the premature infant.] *Ztschr. Kinderheilk.*, 1955, 76, 126-137. [Kinderklin., Med. Akad., Düsseldorf.]

The study included 112 infants of birthweight less than 2300 g., in groups of 2 to 6 beds, not isolated from infection. From birth till jaundice disappeared they were given breast milk, at first diluted with a 5 per cent. sugar solution. Those that did not suck well were fed by indwelling tube. On the 10th day, all had 1.5 mg. vitamin D₃ by intramuscular injection. Those born at home or suspected of perinatal infection had antibiotic treatment [no further information]. There were 3 groups of 31, 31 and 50 infants, given, in that order, a 4/5 reconstituted evaporated cow's milk mixture with 4 per cent. sugar; a 4:1 mixture of breast milk and buttermilk; or breast milk with from 2 to 12 per cent. of undiluted, unsweetened evaporated (cow's) milk added. The third group did best in terms of daily weight gain, condition and absence of infection. In groups 1 and 2 there was a high incidence of interstitial pneumonia, in group 3 none. There was much less craniotabes and dyspepsia in group 3. This confirmed earlier observations.

The absence of fat dyspepsia in these premature infants given the "double" milk is attributed to the homogenisation of cow's milk fat in unheated breast milk containing its natural lipase.

I. Leitch.

5495

GLEISS, J. Zum Frühgeborenenproblem der Gegenwart. [The problem of the premature today.] 9. Über fütterungs- und umweltbedingte Atemstörungen bei Frühgeborenen. [9. Respiratory disturbances caused by feeding and environment in premature infants.] 10. Die Polyvinylchlorid-Dauersonde bei der Prophylaxe fütterungsbedingter Atemstörungen bei frühgeborenen Kindern. [10. The indwelling polyvinyl chloride tube for prevention of respiratory disturbances caused by feeding in premature infants.] *Ztschr. Kinderheilk.*, 1955, 76, 261-268; 269-280. [Kinderklin., Med. Akad., Düsseldorf.]

9. In a group of premature infants of which 256 survived and 133 died, respiratory disturbances were commoner among the former, except in those of birthweight between 2000 and 2250 g. They were mostly of the type clearly associated with feeding and mostly occurred during the first week of life. Accordingly, in a group of 194 prematures of all birthweights, alternate infants were fed for the first time after from 12 to 24 hr., or not fed until there were clear signs of hunger or thirst, as recommended by Gaisford and Schofield (Abst. 2532, Vol. 20). Delay of feeding reduced the incidence of respiratory disturbances due to feeding, but increased the mortality, owing to dehydration, so it is not recommended. Physiological causes of the respiratory disturbances are discussed.

Vol. 25, No. 4

10. Compared with polyethylene, polyvinyl chloride tubing has the advantages of softer edges and resistance to boiling or sterilisation by heat. The same tube can be used for a week. The technique is fully described. Respiratory disturbances of the type associated with feeding did not occur among 389 premature infants fed in this way in the period 1952-54, nor did any other ill effect of tube feeding.—W. M. Deans.

5496

KAGAN, B. M., HESS, J. H., LUNDEEN, E., SHAFER, K., PARKER, J. B. and STIGALL, C. Feeding premature infants—a comparison of various milks. *Pediatrics*, 1955, 15, 373-382. [Kunststadter Labs. Paediat. Res., Sarah Morris Hosp. Child., Michael Reese Hosp., Chicago, Ill.] Spanish summary.

Premature infants of birthweight between 1000 and 2000 g. in 4 groups, 156 in all, were fed is calorically from the 7th to the 28th day, starting at 75 Cal. per kg. bodyweight, on human milk; a 4:1 mixture of human milk and skimmed cow's milk treated with *Streptococcus lacticus*; cow's milk powder modified to resemble human milk in proportions of protein, fat and lactose and in fatty acid composition; or a high-protein, high-ash, low-fat milk consisting of half-skimmed cow's milk with added carbohydrate.

The respective mean daily relative weight gains were 7.92 ± 0.44 (S.E.), 8.59 ± 0.30, 10.56 ± 0.31 and 11.52 ± 0.31 g. per kg. mean bodyweight; the differences between groups were significant, except that between the first 2. The results were similar when infants of birthweight below or above 1482 g. were considered separately, except that with the lighter infants the 2 cow's milk mixtures were equally effective. The differences in weight gain could not be related to energy intake which was planned to be uniform at 82 Cal. per kg. daily, nor to differences in intake of protein, fat or carbohydrate, but a linear relation between weight gain and ash intake was found. Analysis of the results of Gordon *et al.* (Abst. 2357, Vol. 17), who fed their subjects at the higher rate of 120 Cal. per kg. bodyweight daily, yielded a similar result. Other published studies are discussed, and it is suggested that owing to the immaturity of kidney function in premature infants high ash intake may lead to water retention, and that weight gain may, therefore, not be a satisfactory criterion of development.

W. M. Deans.

5497

STRÖDER, J. Leistungsfähige und wirtschaftliche Säuglingsernährung für die Empfehlung des Praktikers. [Efficient and economical infant diet for recommendation by practitioners.] *Münch. med. Wochenschr.*, 1955, 97, 221-224. [Kinderklin., Univ. Würzburg.]

The importance of simple principles in feeding infants is stressed. For healthy infants it is recommended that the diet bulk during the first 3 months of life should not exceed 1/5 of the body-weight, during the second trimester 1/6 and in the third and fourth trimesters 1/7. Five feeds daily are suggested in the early months, to be decreased to 4 by the end of the first year. Diluted cow's milk is preferred for bottle feeding with gruel during the first 3 months and then fruit and vegetable pulp is added. Whole milk may be given by about the eighth month. Juice of orange, lemon, tomato and carrot is suggested as source of vitamin C. The use of proprietary milk preparations and supplements for dyspepsia is outlined and discussed.—A. M. Copping.

SCRIMSHAW, N. S. La leche en relacion con la salud publica. [Milk in relation to the public health.] *Bol. Ofic. sanit. panamer.*, 1954, 37, 522-530. [Inst. Nutric. Centro América y Panamá.]

The nutritive value of milk is discussed with reference to the amounts of protein and vitamins that a supplement of milk could provide for children on poor diets in Central America. The necessity for clean milk and prevention of adulteration is emphasised. The disadvantages of skimmed milk and skimmed milk powder are outlined.

BAPTIST, N. G. and DE MEL, B. V. Growth and amino-acid intakes of children on a cereal-legume-vegetable diet. *Brit. J. Nutrition*, 1955, 9, 156-170. [Biochem. Lab., Dept. Physiol., Univ. Ceylon, Colombo.]

An experiment was made on the feeding of children between 1 and 6 years on an entirely vegetable diet, in which proteins were supplied by

3 cereals (rice, finger millet and wheat flour), 4 legumes (lentil, green gram, black gram and pigeon pea), local vegetables and coconut. Thirty were selected from about 50 children from poor families attending a crèche in Colombo where they got all their weekday meals, but only 23 completed the study. After 15 weeks on the normal crèche diet, one group had the all-vegetable diet and another group the same with $\frac{1}{2}$ oz. dried skimmed milk daily, for 17 weeks; both groups had Ca and vitamin supplements. Details of the diets and of the nutrients and essential amino-acids supplied by them are given. The crèche diet included a little meat and milk but compared with U.S. National Research Council recommendations was low in energy, Ca, vitamin B₁ and riboflavin; the all-vegetable diet with Ca and vitamin supplements was adequate except for Ca and riboflavin. Heights and weights were measured weekly.

No statistically significant difference was found between the group on the all-vegetable diet and that with milk also. The percentage increase in weight per week was significantly greater on both experimental diets than on the crèche diet, and the children showed greater vitality. It was concluded that, at least over short periods, a source of animal-protein factor is not essential for the growth of children. On the crèche diet growth was considered to be limited by shortage not of any one essential amino-acid but of total energy. On the assumption that the all-vegetable diet was adequate in essential amino-acids, a table of amino-acid requirements of children from 1 to 4 and 4 to 6 years on a rice diet under tropical conditions is presented.

The average daily cost of the all-vegetable diet was about 40 cents (7-2d.) per child.

DIETARY SURVEYS AND INDIVIDUAL STUDIES

5503

LATSKY, J. M. The basic approach to the problem of the recognition of human malnutrition. Some personal viewpoints. *S. African Med. J.*, 1955, 29, 291-297. [Union Dept. Nutrit.]

In this review of the usefulness and reliability of nutrition survey work it is argued that the clinician's primary role should be to exclude from a population under study subjects in whom active disease may be contributing to their undernourished condition. Thereafter the remaining subjects can be classified either as normal and adequately fed or as undernourished or malnourished because of the lack or ill balance of certain nutrients in their diets. The criteria may be somatometric or

N.A. and R., October 1955

laboratory measurements supplemented by socio-economic studies.—D. Harvey.

5504

EPPRIGHT, E. S. and SWANSON, P. P. **Distribution of nutrients among meals and snacks of Iowa school children.** *J. Amer. Dietetic Assoc.*, 1955, **31**, 256-260. [Dept. Food Nutrit., Iowa State Coll., Ames.]

The results of a 7-day diet study of 1188 children were analysed for energy and nutrient distribution among meals and snacks. For both boys and girls in each of 4 age groups lunch and dinner each provided about one-third or more of energy and nutrients. Breakfast provided 15 to 20 per cent. and snacks 13 to 17 per cent. of energy, but breakfast provided a higher proportion of nutrients than did snacks. Comparison of the results for the groups with the poorest and with the best diets showed that the disparity was not attributable to differences in any one meal.—F. C. Aitken.

5505

WARNICK, K. P., BRING, S. V. and WOODS, E. **Nutritional status of adolescent Idaho children. 1. Evaluation of seven-day dietary records.** *J. Amer. Dietetic Assoc.*, 1955, **31**, 486-490. [Dept. Home Econ. Res., Univ. Idaho, Moscow.]

Seven-day records of food intake were kept by 274 schoolchildren aged 15 and 16 years. Boys consumed substantially more of all nutrients than did girls. The scarcest nutrients were ascorbic acid and vitamin A.

Statistically significant correlations were found between dietary intake and level in serum of ascorbic acid and between vitamin A intake and level of carotene in serum; significant correlations were not obtained between intakes of vitamin A and riboflavin and their levels in serum.

Commissie tot onderzoek van de voedings- en gezondheidstoestand der Nederlandse bevolking. **Rapport betreffende het onderzoek naar de voedings- en gezondheidstoestand van de**

Nederlandse bevolking in de jaren 1941-1945, uitgezondert de z.g. hongervinter (1944-1945). Deel I, voeding. [Report on the investigation of the nutritional and health conditions of the Dutch people during the years 1941-1945, not including the so-called starvation winter (1944-1945). Part I, nutrition.] Pp. 90. Deel IA, voeding (bijlagen). [Part IA, nutrition (appendices).] Pp. 118. The Hague, 1953.

For this investigation the co-operation of 1979 families was obtained. In Holland at the time there were 2,254,000 families of 2 or more persons. Conclusions were drawn from data for the years 1941 to 1943, as in the next 2 years only part of the country was included in the investigation. The families were given a notebook and small scales and, with the help of trained visitors, they recorded the amounts of foods consumed in one week. These records were lost, but those of nutrient values remained available. For analysis the nutritional unit proposed by the League of Nations in 1936 was amended to take into consideration ages of children and occupations of breadwinners. Though all provinces were represented the numbers from different provinces were not proportionally correct. Seven occupational groups were listed: artisans, clerks, shopkeepers, professional people, agricultural labourers, farmers and nationally assisted persons. The amount of food consumed was found to vary within the occupational groups, increasing or decreasing with the incomes, except for professional people and assisted persons, where hardly any variation occurred within the group.

The energy value of the food consumed was below the range ± 15 per cent. of the standard recommended by the Education Bureau of the Nutrition Council in 35 per cent. of farmers' families and for all assisted persons; other groups showed values between those extremes. The mean intake was 3000 Cal. for farmers and 2000 Cal. for assisted persons. Energy intake fell for all groups in the years 1941 and 1942, but in 1943 it did so only in those families which previously had consumed fairly large amounts of food. The decrease was due mostly to a considerable fall in intake of fat, partly compensated by an increased intake of carbohydrate. The total amount of protein consumed remained fairly steady, but animal proteins tended to be replaced by vegetable proteins. Vitamin A intake was below normal in 50 per cent. of assisted persons and in 10 per cent. of professional people, with intermediate values for the other groups. Intake of vitamin B₁ was almost normal. Ascorbic acid intake varied with the season, normal values being found everywhere when fruit was plentiful; in winter intake was low for all assisted persons. With a norm of 1100 mg. Ca per man value, from 75 to 90 per cent. of the assisted families and between 15 and 70 per cent.

38

of the others did not reach that level. The intakes ranged from 800 to 1500 mg. daily. Fe intake increased from 1942 to 1943 and was rarely found to be below normal, the range being from 17 to 23 mg. daily. Variations in intake of nutrients in different regions were greatest in 1941.

M. Eddison.

DEN HARTOG, C., NASS, C. A. G. and FRETZ, F. W. Onderzoek naar de voeding van de Leidse studenten. [Study of the diet of the Leyden students.] *Onderzoek. Meded. Nederlands Inst. Praev. Geneesk.*, 1955, pp. 38.

An inquiry by the Central Bureau of Statistics into the social conditions of students of the University who were living in Leyden showed that 42 per cent. of them did not have an adequate hot meal every day; it prompted this fuller investigation. In February 1950 a lengthy questionnaire was sent to all 4914 students registered for the academic year and 2900 replies were received; a second approach brought 90 more which were suitable for study. In the analysis a system of points was allocated according to the quality of the meals.

The number of students having one hot meal daily was 53 per cent. of the total; most had it in the evening. The adequacy of the meals of students living at home was greater than of those in rooms and first and sixth year students fared better than those of other years, the second-year ones being poorest. In rooms women students did better than men, although men spent more on their meals and gave lack of money as a reason for their inadequacy. In points awarded for beverages with emphasis on milk, men scored more than women, but for consumption of fruit the opposite was true.—M. Eddison.

5509

MONTINI, L. The parliamentary inquiry into destitution in Italy. *Internat. Labour Rev.*, 1955, 71, 60-78.

The author was vice-president of the commission of inquiry into destitution set up in 1951. The inquiry included a survey of the living conditions of 58,000 families representing all social classes and all parts of Italy, and a more detailed survey of 2000 destitute families receiving government assistance and representative of town life; the findings are briefly reported in some 3 pages of this article.

From the first survey it was estimated that 11.8 per cent. of all families (6 million people) had a "very low" standard of living; about half of these consumed no meat, sugar or wine, and the rest but little. Clothing was as bad, and housing even worse. About the same number had a "low" standard of living; 11 per cent. of them had no meat, sugar or wine. The two groups

together account for about a quarter of the population. Though families in these categories are found everywhere, in the south they amount to half of all families and in the islands to nearly as much.

The detailed survey showed that the average monthly expenditure of a poor town family of 2 adults and 2 children was 27,628 lire, of which 62 per cent. went on food, in contrast to 65,656 lire for Fiat workers in Turin and 56,764 lire for workers in Trieste found in contemporaneous inquiries and the hypothetical figure of 64,937 lire used to calculate the cost of living indices on which wage scales are based. The average daily consumptions were 2500 Cal. (Fiat workers 3140, workers in Trieste 3282); animal protein 19 g. (Fiat workers 49, Trieste workers, no figure given); fat 63 g. (91, 101); carbohydrates 390 g. (452, 396). For larger families the results were worse, and poor families in the south had barely 2270 Cal. with only 8 g. protein.—W. M. Deans.

5510

CLARK, F., MURRAY, J., WEISS, G. S. and GROSSMAN, E. Food consumption of urban families in the United States with an appraisal of methods of analysis. *U.S. Dept. Agric., Agric. Inform. Bull.* No. 132, October 1954, pp. vi + 203.

In 1948 and 1949 there were made in the United States a nation-wide survey of 1558 urban families, a survey of 1066 families in the 4 cities Birmingham, Ala., Buffalo, N.Y., Minneapolis-St. Paul, Minn. and San Francisco, Calif. and seasonal surveys, 1865 in number, of selected families in these same cities. Records were made over 1 week. The present report is in 2 parts.

The first part (pp. 2 to 13) gives the findings and compares them with results obtained in 1942 in a similar study (Family Food Consumption in the United States. Spring 1942. *U.S. Dept. Agric. Misc. Publ.* No. 550, 1944). Total expenditure on food in the spring of 1948 for the nation-wide study was, on the average, about \$26 per family of 3.29 persons; the average income before deduction of income tax was \$80 for the week. The mean cost of food eaten away from home was about \$4 per family. As a percentage of income expenditure on food was in the \$1000-2000 class 45 and in the \$5000-7500 class 24.

Average amounts of the more common foods purchased weekly per family were, milk 10.6 qt., eggs 1.8 doz. and, in lb., processed milk 1.6, cheese 1.0, bread 6.1, meat 10.5, sugar 2.9, fresh fruit 11.8, potatoes 7.0, fresh vegetables 9.2. Only for frozen fruits and vegetables, fresh fruits and beverages was income elasticity of expenditure so high that with a 10 per cent. difference in income there was as much as a 3 per cent. difference in expenditure. There was evidence that consumption

of milk by many of the children was probably below the amounts recommended. Seasonal variation in consumption was greatest for fruit and vegetables; for other groups of foods it was small.

The changes in food consumption between 1942 and 1948 were studied by dividing the families into 3 groups according to income. Consumptions of citrus fruit and tomatoes and of meat, poultry and fish increased considerably in the group with the lowest but changed little in that with the highest income. Consumption of sugar and sweets increased by 60 per cent. in the lowest and by 36 per cent. in the highest group because, it is thought, of the removal of rationing. For potatoes and sweet potatoes consumption declined by about 20 per cent. in all 3 groups.

In part 2 of the report (pp. 14 to 53) the problems and methods of analysing family food data are considered. Appendix A (pp. 55 to 173) contains 56 tables prepared from the data, Appendix B gives the methods used in collecting the data and in Appendix C the forms used in the survey are reproduced.—D. Harvey.

5511

CLARK, F. and LeBOVIT, C. B. **Food consumption of farm families, Meeker and Wright Counties, Minnesota, 1950.** *U.S. Dept. Agric., Agric. Information Bull. No. 127, January 1955*, pp. vii + 112.

A diet study was made in spring 1950 of 235 farming families; the data were for comparison with those collected in 1948 and 1949 for urban districts in the same State (see preceding Abst.). The recall method was employed for recording foods used in the preceding week. Income was mainly from the sale of dairy, livestock and poultry products and, after deduction of taxes, was, for more than half of the families, below \$2000 in 1949.

The average total money value of food for the week was \$18.88 per family of 2.64 persons. The value of food eaten away from home was \$0.61 per family. Mean amounts for some of the groups of foods used were, per household, milk (equivalent of all forms) 16.7 qt., eggs 2.2 doz. and, in lb., flour and cereals 5.8, bakery products 5.2, meat, poultry and fish 11.1, fresh fruit 6.4, potatoes 11.9 and fresh vegetables 3.7. On the average the U.S. National Research Council's recommended allowances (1948) for 9 nutrients were met, but diets were deficient in Ca and ascorbic acid for about one-third of the families and in vitamins A and B₁ and nicotinic acid for about one-sixth.

Comparison of country and city families showed that total money values of diets were about the same but that actual expenditure on food by country was only about half that by city families. The farming families used more grain products, fats, sugar, potatoes, milk and eggs but less fruit

and vegetables; their energy intake was greater and their amounts of vitamins A and C were less than those for city families. There was little difference in the extent to which the groups of families used foods which were bought ready processed.—D. Harvey.

5512

BABCOCK, M. J., CHURCH, H. N. and GATES, L. O. **Nutritional status of industrial workers. 2. Effects of education, age, income, and ethnic groups.** *Milbank Mem. Fund Quarterly*, 1955, **33**, 137-151. [New Jersey Agric. Exp. Stat., Rutgers Univ., New Brunswick.]

For part 1 see Abst. 2567, Vol. 25.

The effects on nutritional status of education to 4 grades, of age grouping in 3 categories and of income at 3 levels were examined by appropriate analyses of data used in earlier studies. The differences were found to be slight, the evidence being that intakes of Ca and P and the amounts of ascorbic acid in blood serum were greatest for those whose educational grade was highest, that intake of vitamin B₁ fell with advancing years and that low intakes of Ca and ascorbic acid were associated with low levels of income. It is concluded that when education in nutrition is to be provided it should be made available at all levels of educational attainment, age and income.

D. Harvey.

5513

McGANITY, W. J., BRIDGFORTH, E. B., MARTIN, M. P., NEWBILL, J. A. and DABBY, W. J. **The Vanderbilt cooperative study of maternal and infant nutrition. 8. Some nutritional implications.** *J. Amer. Dietetic Assoc.*, 1955, **31**, 582-588. [Dept. Biochem., Sch. Med., Vanderbilt Univ., Nashville, Tenn.]

For Part 7 see Abst. 4111, Vol. 25.

The mean daily energy intakes of the subjects were 2140, 2200 and 2020 during the 1st, 2nd and 3rd trimesters, respectively. The need for an increment of 400 Cal. to meet "the hypothetical enhanced need of late pregnancy" is questioned; and it is concluded that the maximum energy intake is not, as is commonly supposed, during the third trimester. Of the patients studied 27 per cent. were given supplements; except for women with Fe-deficiency anaemia, to whom a supplement of Fe was of indisputable value, they did not differ from the unsupplemented group in respect of the incidence of maternal or foetal complications. The only physical finding which could be correlated with dietary or biochemical values was gingivitis; its incidence was about 30 per cent. when either the ascorbic acid intake was below 20 mg. daily or the level in the serum was below 0.2 mg. per 100 ml.; but even with very adequate dietary or serum ascorbic acid values the incidence of

gingivitis was still about 20 per cent. The relation of nutrition to abnormal obstetric conditions is summarised (see also Abst. 5103, Vol. 24), and the clinical findings are discussed in relation to energy and to protein intake. There was an increased incidence of pregnancy disease and of pre-eclampsia and eclampsia when intakes of energy and protein during the 3rd trimester were less than 1500 Cal. and 50 g.; it is emphasised that the disorders appeared "to be responsible for the lowered intake and not vice versa".—A. M. Thomson.

5514

STRAW, K. H. **Household budgets and nutritional analysis of food consumption in Barbados.** *Social Econ. Studies*, 1954, **3**, 5-38.

Household expenditure in Barbados tends to be seasonal, occurring more in what is known locally as the "crop season", 20 weeks between January and June when income derives from the sugar harvest, than in the "hard times", the remaining 32 weeks of the year. For the preparation of a cost-of-living index budgets were obtained from 1417 households of which 1336, 94.3 per cent., had weekly incomes of \$49 or less ($1\$ = 4s. 2d.$). From the data for these latter and with certain allowances for housing and clothing, since only 20 per cent. were paying rent and new clothes were generally bought in November and December, the average weekly pattern of expenditure per household weighted for season was calculated.

Average total expenditure was \$16.83, of which 50.8 per cent. was on food and accounted for by 12.3, 12.4, 4.7, 1.4, 3.3, 9.6, 0.5, 0.8, 3.2 and 2.6 per cent., respectively, on meat and fish, grain products and legumes, vegetables, fruit, sweets, dairy products with oils and fats, proprietary foods, condiments, beverages and food bought and eaten away from home. The highest individual items of expenditure were, in cents of a dollar, on rice 64, women's dresses 56, sugar 53 and bread 41. When expenditure within seasons was compared average weekly amounts were \$16.38 in "hard times" and \$15.29 in "crop season"; only in the food group was expenditure greater in "crop season" than in "hard times".

The nutritive value of the average diet was calculated after food purchased away from home had been distributed uniformly over the whole group and an allowance had been made for home-produced foods. Deficiencies which could be regarded as significant were found for Ca, riboflavin, vitamin A and animal protein, but the calculations were without reference to the nutrients in milk and yeast biscuits supplied to schoolchildren, in sugar cane chewed freely in the "crop season" and in the drinking water, which had 81 p.p.m. Ca.

The conclusion is that, on the basis of the proportion of income spent by its population on food,

Barbados is better off than the poorest but is a long way behind the richest countries of the world.

CHIRIBOGA, C. C. **La dieta del indio. [The diet of the Indian.]** *Arch. venezol. Nutrición*, 1954, **5**, 343-346. [Dept. Nutrit., Minist. Salud Púb., Peru.] English and German summaries.

The diet of Peruvian Indians appears since at least the sixteenth century to have violated all the laws of nutrition. Maize is the staple food. Next in importance is quinoa (*Chenopodium quinoa*), a small grain which is fairly rich in protein and rich in P and Fe and has good contents of Ca and of some B vitamins. In growth experiments with rats its protein had a biological value as high as that of milk protein at the 9 per cent. level. It was not improved by additions of tryptophan and leucine.

It is concluded that the Indians may have become adapted to a low protein intake, and that the high value of quinoa has probably helped their survival.

- The term "antinutrients" is preferred to "antimetabolites". There are several groups. Antivitamins are of 4 types; vitamin analogues which block the action of the vitamin, substances like salicylic acid with no chemical relation to any vitamin, those which precipitate vitamins in insoluble form or otherwise inactivate them, and vitaminases.
- Substances such as phytin and oxalic acid are considered as antiminerals. The role of an antinutrient is also ascribed to alcohol, as an antagonist of sugar. Poor digestibility of some foods may be due to the presence in them of such antinutrients.

MOSQUEDA SUÁREZ, A. La arepa criolla. [Criollo maize bread.] *Arch. venezol. Nutricion*, 1954, 5, 407-423. [Inst. Nac. Nutric.] English and German summaries.

The form of maize bread called *arepa* has greater importance in Venezuela than in the neighbouring countries. It is almost always prepared at home, though in Caracas there are a few places where it is produced industrially. The method of preparation is described; usually the cuticle and part of the germ are removed before the maize is washed, dried and ground. The flour is mixed with water and salt and the *arepa* is baked on an iron or clay girdle [flat plate] over a wood fire.

The composition of 16 samples of *arepa* is given in a table. They contained, per 100 g., 3.76 to 6.18 g. protein, 10.9 to 211 mg. Ca, 23 to 154 mg. P and 1.4 to 6.6 mg. Fe. The percentages of the requirements for an adult man of 65 kg. met by 100 g. *arepa* were energy 5.19 to 6.7, protein 6.4 to 9.5, Ca 2.2 to 9.4, Fe 11.7 to 28.8, carotene 0.12 to 1.4, vitamin B₁ 1.25 to 7.5, riboflavin 1.3 to 3.1 and nicotinic acid 0.8 to 3.4.

It is considered that the maize should be enriched with Fe and the above 3 vitamins of the B complex. Four experiments in enrichment were made and the cost was worked out.

The economic importance of *arepa* and the organisation of a campaign for maize enrichment are discussed.—D. Duncan.

HAIGHT, T. H. and PIERCE, W. E. Effect of prolonged antibiotic administration on the weight of healthy young males. *J. Nutrition*, 1955, 56, 151-161. [Naval Med. Res. Unit No. 4, U.S. Naval Training Centre, Great Lakes, Ill.]

Six companies each of 55 Navy recruits were arranged at random in 3 groups. All the subjects received once daily for 7 weeks one of 3 preparations identical in appearance and consisting of 250 mg. of aureomycin, 100,000 units of buffered procaine penicillin or a calcium carbonate placebo. Records of nude height and weight were made at the start of the experiment and after 4 and 7 weeks. Calculations were made for individual and group weight changes, both actual and relative to the standard weight for age and height. The final data were available from 310 subjects.

Changes after 4 and 7 weeks revealed a distinct difference in favour of the antibiotic groups; the differences between the aureomycin and the penicillin group were not significant. The average change after 7 weeks was 4.8 lb. for the aureomycin, 4.1 lb. for the penicillin and 2.7 lb. for the placebo group.

To estimate normal group to group variation a similar study was made in which no treatment was given; in this experiment no significant difference was found.—G. F. Garton.

WALSH, R. M. A further note on methods of increasing domestic consumption of farm products. *J. Farm Econ.*, 1955, 37, 110-114. [Market Development Branch, U.S. Dept. Agric.]

Some of the suggestions made by Wilcox (Abst. 2608, Vol. 25) are elaborated. It is stated that an increase in consumption of about one-fourth or one-third among the poorest tenth of the population would absorb most of the present U.S. agricultural surpluses.—W. M. Deans.

5542

FOX, F. W. Agricultural foundations of nutrition. 12. Conclusion. *S. African Med. J.*, 1955, 29, 282-284. [S. African Inst. Med. Res., Johannesburg.]

Besides the purely agricultural aspects discussed in earlier parts (see Abst. 4068, Vol. 25) other conditions must be considered. The Conservation Act of 1946 has done much to counteract misuse of the soil but, economically, stability of prices must be ensured and, socially, rural amenities must be provided, if the business of farming is to maintain its attractiveness in competition with urban life.—D. Harvey.

5543

NEL, L. W. A. Food balance sheet of the Union. *Farming in S. Africa*, 1955, 30, 10-12. [Div. Econ., Pretoria.]

The provisional food balance sheet for 1953 shows that for 13,153,000 people in the Union of South Africa 6,080,100 short tons of food were available, providing, daily, 2748 Cal., 73.88 g. protein and 64.22 g. fat. Comparison is made

with data for the period 1935 to 1939 and with annual values since 1947. Increase in amounts of food has resulted in the energy available per head being 20 per cent. greater than before the war.

5544

ROUX, R. An approach to minimum wage fixing in Guatemala. *Internat. Labour Rev.*, 1955, 71, 1-33. [Internat. Labour Office, Geneva.]

In this account of the work of an I.L.O. technical assistance mission which visited Guatemala in 1951-52 to advise on the introduction of a minimum wage, there are 3 pages on food costs. From earlier investigations, the typical working-class family was assumed to consist of parents and 3 children in towns and parents and 4 children in the country and to spend 63 per cent. of its income on food. The minimum nutrients per consumer unit daily recommended by the Institute of Nutrition for Central America and Panama for town and country people, respectively, were: Cal. 2600, 3000; total protein 78, 79 g., of which 20 g. was animal; Ca 0.7, 0.9 g.; Fe 23, 20 mg.; vitamin A 4250 I.U. for both; vitamin B₁ 1.4, 2.7 mg.; riboflavin 1.0 mg. for both; nicotinic acid 15, 18 mg.; ascorbic acid 75, 50 mg. Tables give the amounts of foods required to provide a town and a country family with these. In February 1952 the town family diet for a week cost 8.07 quetzals in Guatemala City, and by allowing for other expenditure a minimum living wage of 1.83 quetzals a day was deduced.

The minimum wage eventually fixed for the textile and garment industries throughout the country, including home-workers, was 1.25 quetzals a day.—W. M. Deans.

EDWARDS, D. A. W., HAMMOND, W. H., HEALY, M. J. R., TANNER, J. M. and WHITEHOUSE, R. H. Design and accuracy of callipers for measuring subcutaneous tissue thickness. *Brit. J. Nutrition*, 1955, **9**, 133-143. [Dept. Clin. Res., University Coll. Hosp. Med. Sch., London.]

Preliminary experiments with callipers of the Franzen type suggested the following recommendations: (1) the faces should be rectangular and of size 6×15 mm., with well rounded edges and corners; (2) the pressure exerted at the faces should not vary by more than 2.0 g. per sq. mm. over the range of openings from 2 to 40 mm.; (3) a standard pressure of 10 g. per sq. mm. should be applied; (4) readings to the nearest 0.5 mm. and preferably to 0.1 mm. should be possible. A commercial callipers adapted to conform to these specifications was tested. For conversion to a logarithmic scale the formula

$$z = 100 \log_{10} (\text{reading in tenths of 1 mm.} - 18)$$

was used, for which a table is reproduced. It was found that standard deviations of the differences between duplicate readings by one observer at the triceps, subscapular and supra-iliac sites were from 2 to 4 units, equivalent to 0.3 to 0.6 mm. at a jaw opening of 7 mm. When the sites were marked on the bodies of subjects the equivalent figures for different observers were roughly twice as large. It is considered that these modifications will eliminate all important instrumental sources of error and that experimental error would be almost entirely that due to differences in picking up skinfolds, which could be reduced "by rigorous specification of technique and training of observers". Of the sites tested in these trials, the biceps seemed to be least satisfactory, the triceps and subscapular fairly good and the supra-iliac site intermediate.—A. M. Thomson.

5546

NEWMAN, R. W. Skin-fold changes with increasing obesity in young American males. *Human Biol.*, 1955, **27**, 53-64. [Quartermaster Res. Development Centre, Natick, Mass.]

Skin-fold measurements were made on recruits to the United States Army before their basic training; of the men 1702 were white and 292 negroid. The average age was 20.7 years, range 17 to 28. The sites selected for measurement were: chest, above and to the right of the right nipple; arm, on the back and halfway up the upper arm;

back, immediately below the right scapula; abdomen, to the left of the navel; and thigh, above the right kneecap. Measurements were made 3 times in each site by each of 2 technicians and value was taken.

The results showed no reason why body fat of negroes should not be calculated on the same equation as that of whites, but there was a relative lack of obese negro subjects, so data on these are inadequate. Among those whose combined skin-fold value on abdomen, arm and chest totalled 45 mm. or less the lines for mean values for each thickness when plotted against the sum for the 3 areas closely approximated to straight lines; differences between races were not significant. The negroid group had low values for chest and arm and high values for abdomen and the differences in fat distribution were visible.

When all the subjects were considered together the deposition of fat became relatively greater on the torso than on the extremities as obesity was greater. This is probably because of physical limitation of storage space in the extremities.

PRATT, A. G. and READ, W. T. (Jr.) Influence of type of feeding on pH of stool, pH of skin, and incidence of perianal dermatitis in the newborn infant. *J. Pediat.*, 1955, **46**, 539-543. [Maternity Nursery, Cooper Hosp., Camden, N.J.]

The pH of stool, of the peri-anal skin after cleaning with water, and of the axillary skin was tested in 251 babies aged between 2 and 9 days. One hundred and forty were breast fed, 50 were fed on a mixture which simulated breast milk and in which lactose was the sole carbohydrate and 61 were fed on a mixture of cow's milk, maltose and dextrin. There was little difference between the groups in stool pH, which was just over 6 during the first 3 days of life; after the fourth day the mean values for pH of stool and peri-anal skin fell

N.A. and B., October 1955

in the babies on breast or simulated breast milk, but altered little in those given the cow's milk mixture. There was a wide range with considerable overlapping, but the differences are said to be statistically significant. The axillary skin *pH* became more acid with age in all groups.

The percentage incidence of peri-anal dermatitis was 7.1 in breast-fed infants, 14.0 in those on simulated breast milk and 19.7 in those on the cow's milk mixture. It is concluded that this supports the belief that the incidence of peri-anal dermatitis is greater when the stool is more alkaline, although there was no real difference in *pH* between the stools in breast milk and simulated breast milk groups.—F. E. Hytten.

JEANS, P. C., SMITH, M. B. and STEARNS, G. Incidence of prematurity in relation to maternal nutrition. *J. Amer. Dietetic Assoc.*, 1955, 31, 576-581. [Dept. Paediat., Coll. Med., State Univ. Iowa, Iowa City.]

Pregnant women of low income, living in a predominantly rural area and numbering 404, whose dietary habits had been studied (Abst. 1064, Vol. 22), gave birth to 28 premature infants. Of these, 4 were twins and 4 were severely deformed. One was stillborn and deformed and 5, including 2 deformed, died. All the deaths and deformities were among infants of women whose diets were classified as poor or very poor, and the incidence of prematurity was strikingly high in women on very poor diets. Among the better nourished, prematurity tended to be associated with frequency

and high total number of pregnancies, and with multiple births; all their premature infants lived and were in good condition when leaving hospital. A. M. Thomson.

LOWENSTEIN, F. W. A study of blood pressure in relation to diet in Chinese and Caucasian students in New York City. *Amer. Heart J.*, 1955, 49, 562-580. [Columbia Sch. Pub. Health, New York.] Interlingua summary.

Chinese students born in the Orient but living in the United States were selected and grouped according to their dietary habits. The types of diets and the numbers of men and women, respectively, in the groups were: Chinese diet, 32, 17; mixed Chinese and American diet, 40, 16; American diet, 38, 19. In a fourth group were 70 male and 30 female Caucasians on American diet. Medical histories were taken to exclude any with signs of hypertension and to provide information on the occurrence of cardiovascular or renal disease in their parents. Weight, height and chest circumference were recorded and blood pressure was measured at 4 periods of the year. Mean data and comparisons between groups are summarised for each period.

In physical characters for both sexes Chinese were smaller than Americans. Cardiovascular and renal disease was more common in parents of Caucasians than of Chinese.

Mean blood pressures were lower for Chinese than for Caucasian men but no significant difference was found for women. Data were thought to be too few to allow the difference to be attributed to diet. For both sexes and in all groups blood pressure fell in successive periods, but the fall was not seasonal since it did not take place at the same examination in each group, but in Caucasians at the earlier and in Chinese at the later dates. Sex differences were smaller among

Chinese than among Caucasians and may have been due to the preponderance of femaleness in Chinese males, the endocrine aspects of which are suggested as deserving further study.

PAQUIN, A. J. The rate of body weight loss following surgical stress of uniform intensity. *Ann. Surg.*, 1955, 141, 383-387. [Dept. Surg., Cornell Univ. Med. Coll., New York.]

The surgical stress studied in 12 comparable men with carcinoma of the bladder was radical total cystectomy performed by surgeons of similar skill. Weight was measured under standard conditions immediately before anaesthesia was induced and at daily intervals after operation. It was found that, in general, loss of weight occurred for between 7 and 30 days, after which weight was fairly constant. Rate of loss was expressed in terms of daily loss per kg. initial weight and was corrected to 70 kg. For comparison Benedict's data (*Carnegie Inst. Washington Publ.* No. 203, 1915) for fasting subjects were used.

Although the total number of subjects was small, loss of weight appeared to be uniform, an average of 4.1 g. per kg. daily with range from 2 to 6 g. for the patients, with a corresponding amount of 6.26 g. for the fasting subjects.

D. Harvey.

5558

COOKE, A. M. Osteoporosis. *Lancet*, 1955, 268, 877-882; 929-937. [Radcliffe Infirmary, Oxford.]

A shortened version of the Lumeian lectures for 1955 delivered to the Royal College of Physicians of London is reproduced with 143 references. Inpatient records of Radcliffe Infirmary and some other sources provided 50 cases of spinal osteoporosis in 43 women and 7 men. Their age distribution, males and females, respectively, in decades from 30 years upwards was 1, 1: 0, 4; 3, 8; 2, 11; 0, 15; 1, 3; 0, 1. The preponderance of females points to an endocrine effect. Of these patients 37 were given hormones, most of them both oestrogens and androgens; 5 had oestrogens only and 3 androgens only. Later information was obtained from 27, of whom all but 4 reported subjective improvement. In view of the large number of elderly people likely to be similarly affected the encouragement of some physical activity and the maintenance of adequate intakes of protein, Ca and P should be borne in mind by those responsible for their care.

WILKINSON, J. The diagnosis of onyala. *East African Med. J.*, 1954, 31, 549-556. [Church

of Scotland Mission Hosp., Tumutuini, P.O. Karatina, Kenya Colony.]

The 3 conditions from which onyala may be distinguished are thrombocytopenic purpura, scurvy and the bite of certain snakes. The blood bullae which form in the mouth are typical for diagnostic purposes.—E. M. Hume.

5560

HARRIES, J. R. A case of onyala in a male Taita showing diminution or absence of megakaryocytes. *East African Med. J.*, 1954, 31, 557-559.

A mild case of onyala is described. The unknown causative factor apparently depressed the formation of megakaryocytes by the reticulo-endothelial system, and did not destroy the platelets after their liberation into the peripheral bloodstream. The same factor probably caused an increase in the capillary permeability. The effects of the factor were short-lived, and it is improbable that the treatment given with ascorbic acid and vitamin K had any effect. The cause is thought to have been endogenous.—E. M. Hume.

DEFICIENCY DISEASES

General

5561

PORTILLA, J. M. Síndrome pluricausal infantil. [Multiple deficiencies in infants.] *Arch. venez. Nutrición*, 1954, 5, 463-467. [Inst. Nac. Nutrición, Quito, Ecuador.] English and German summaries.

Five infants with multiple deficiencies of different types were treated in Quito. One was believed to have kwashiorkor, not previously described from Quito, and a later visit to the district from which it came showed that in some families all the children seemed to have kwashiorkor.—D. Duncan.

5562

DEMAEYER, E. M. and VANDERBORCHT, H. Évolution de la courbe pondérale et de certains constituants biochimiques et hématologiques du sang dans le kwashiorkor. [Course of the weight curve and of certain biochemical and haematological constituents of the blood in kwashiorkor.] *Ann. Soc. belge Méd. trop.*, 1954, 34, 417-432. [Inst. Recherche Sci. Afrique Centr., Centre Kivu-Lwiro, Belgian Congo.] English and Flemish summaries.

A study was made of 79 infants aged from 1 to 6 years with severe kwashiorkor; nearly all suffered from intestinal parasites and malaria and many had a congestive lesion of the lung. In 3 age groups, 1½ to 2, 2½ to 3 and 4 to 6 years, they were treated with a skimmed milk diet which was

gradually increased to be a high-protein, mixed diet yielding 150 Cal. per kg. bodyweight daily by the 15th to 20th day, according to the individual child's response. After the disappearance of oedema the mean weight of the infants in all groups was significantly lower than the standard weight of healthy American or Uganda children of the same age group, but the daily weight gain under treatment was much in excess of the gain in normal children. Serum proteins were estimated in the 79 infants on admission and in 55 on discharge; in 24 the changes in the albumin fraction during treatment were followed in detail. As in other series, the total protein and albumin were reduced on admission and rose on treatment. Analysis of the data showed that the regeneration of albumin was a function of the logarithm of the time under treatment, from which it was possible to determine how long any child would have to remain in hospital before the albumin reached a given level.

Serum amylase was estimated in a small number of the patients and was significantly lower than in healthy members of the local population and also than the corresponding American values; the value rose rapidly in the first few days of treatment, remained stationary for about 5 weeks and then rose further. Cholesterol and cholesterol esters also were low on admission and rose during treatment. Haematological studies showed moderate anaemia associated with raised mean corpuscular volume and reduced mean corpuscular Hb concentration. There was only a very moderate improvement in the anaemia while the child was in hospital. The findings are discussed. The methods used and the values obtained are described in detail.

DUFOUR, G. and DUFOUR, Y. Observations sur la croissance des nourrissons et sur quelques aspects de carence alimentaire à La Réunion. [Growth of infants and some aspects of nutritional deficiency in the island of Réunion.] *Méd. trop.*, 1954, 14, 741-748.

Vital statistics of Réunion showed a high infant mortality rate which had remained stationary in spite of an intensive antimalarial campaign and improved antenatal care. The mortality rate for the age group from 1 to 5 years also was very high. Examination of pregnant women in 1952 showed, in addition to severe undernourishment, an enlarged heart in 20.2 per cent.; the percentage fell to 8.4 in 1953 when whole rice had replaced polished rice, rice being the staple diet of the people. Other signs of deficiency of the vitamin B complex were common. Cirrhosis of the liver was absent from the adult population, but a condition diagnosed as kwashiorkor was frequent in young children. The malnutrition was probably of

recent origin and due to the sudden large increase in the population which followed the antimalarial campaign and caused extreme poverty. During the cane harvest the state of nutrition improved; at the same time the mean birthweight rose above that found in other months. Weaning was general at 8 months; a marked flattening of the weight curve followed weaning, and the kwashiorkor syndrome was frequently seen. The most severe cases were among the white or coloured, not among the African, infants.—L. Wills.

WOŹNIAK-TORBIK, E., PUDLIK, K., SZCZYGEŁOWA, M., BERGER, S. and SZCZYGEŁ, A. Sezonowe wahania w stanie odżywienia młodzieży żywnościowej zbiorowo lub indywidualnie. [Seasonal variations in nutritional status of children living in school boarding houses or in their parents' homes.] *Rocz. Państwowego Zakł. Hig.*, 1955, 6, 23-32. Russian and English summaries.

From December 1951 to November 1952 a periodical assessment was made of the nutritional status of high school children, one group living in the school boarding house and the other at home, to see if there was any seasonal variation.

Signs of vitamin A deficiency were found clinically in only 2 per cent. of the children in the boarding house; the absence of any sign is attributed to the distribution of cod liver oil during the winter. Vitamin C deficiency occurred in 7 per cent. during the winter and in 2 per cent. in the autumn. Signs of riboflavin and nicotinic acid deficiencies were noted more often in winter than at any other period. Biochemical examination confirmed the clinical findings.

In a group of children attending high school for the first time, clinical and biochemical signs of vitamin A, riboflavin and nicotinic acid deficiencies were less frequent than in the boarding house children, but there were more cases of vitamin C deficiency. (From summary.)—J. S. Thomson.

5566

FIELD, C. E. Nutritional problems in the Federation. *Med. J. Malaya*, 1955, 9, 179-194. [Penang.]

In this lecture nutritional disorders found in young children in Malaya are reviewed and, of a number of questions posed, 2 are discussed in more detail. The clinical manifestations of beriberi are

so variable that the condition appears to require further investigation. Kwashiorkor in classic form is not, in the author's experience, widespread, but findings in 8 cases are quoted to show that minor degrees of it are common and that, when either severe infection or infestation with roundworm is superimposed, the complete picture will generally appear.—D. Harvey.

5567

USBORNE, V. **Home and dispensary findings in a survey of Wasukuma children.** *East African Med. J.*, 1954, 31, 531-536. [E. African Med. Surv.]

A survey was made in their own homes of 629 children under 11 years of age, belonging to the Sukuma tribe, living in the Kwimba district of Sukumaland in Tanganyika, just to the south of Lake Victoria. Maize, millet and sweet potatoes are the common crops. The survey included other than nutritional conditions. Kwashiorkor was not seen. The number of children with xerosis was 60, dental caries of the milk teeth 17, hypochromotrichia 128, fluorosis 11 and indented tongue 9.—E. M. Hume.

5568

GUNASEKARA, D. B. **Nutrition studies of a prison population.** *Ceylon Med. J.*, 1954, 2, 224-233. [Med. Res. Inst., Colombo.]

A nutritional study of 638 inmates of a prison in Ceylon included a single clinical examination, especially for signs of vitamin deficiency, a record of weight and an estimation of the nutrients in the diet. Choice of diet, vegetarian or non-vegetarian, was permitted and change from one to the other allowed. Little difference existed between the diets; their respective protein contents were 84 and 96 g.

After the examination reference was made to weights at admission which were available for 391 men; analysis of the data showed that they formed a group representative of the whole population. Of the 391 inmates, 244 had gained, 124 had lost and 23 had not altered in weight since admission; the evidence was that, with reference to weight on admission, it was probable that men under 120 lb. would gain, those between 120 and 140 lb. would show no change, and those over 140 lb., of whom there were few, would lose. Duration of stay appeared not to affect weight change.

Signs of vitamin deficiency were grouped in relation to length of stay. During the first year xerophthalmia, phrynoderma, angular stomatitis and glossitis were less frequent; phrynoderma was commonest between 1 and 4 years; sore canthi were less common under 2 years. In general, signs of deficiency of vitamin A and riboflavin were

relatively infrequent under 1 year; the vegetarian and non-vegetarian diets contained, respectively, 2330 and 2315 I.U. vitamin A and 0.87 and 0.92 mg. riboflavin. Only with phrynoderma was the association of mosaic skin statistically significant. There was no significant difference in the prevalence of any condition among men who gained, lost or showed no change in weight.—D. Harvey.

SANDSTEAD, H. R., KOEHN, C. J. and SESSIONS, S. M. **Enlargement of the parotid gland in malnutrition.** *Amer. J. Clin. Nutr.*, 1955, 3, 198-214. [Lab. Biochem., Nat. Inst. Arthritis Metabol. Dis., Nat. Inst. Health, Bethesda 14, Md.]

The populations studied were 3168 Asians in a field study (Sandstead and Koehn, to be published), 1094 patients in a mental hospital in District of Columbia and 165 Indian patients at mission hospitals in New Mexico and Arizona. In these respective groups the incidence of enlargement of parotid glands was 13.7, 3.5 and 12 per cent. The glands were not tender or painful. Some histological and tissue culture examinations were made; although these were few, the hypertrophy appeared to be non-inflammatory and due to a swelling of individual cells with, in the chronic stage, replacement of acinar tissue by fat.

From the information available from diet studies intakes of energy were sometimes low and those of fat and vitamins A, B₁ and C and riboflavin were probably inadequate. The conditions with which the enlargement was generally associated were those of underweight, cheilosis and pellagroid pigmentation when present together, and, to lesser degrees, calf muscle tenderness and anaemia.

Vitamin A

5575

BERGER, S. and SEGAL, P. Współzależność adaptacji i poziomu witaminy A w surowicy krwi. [The mutual dependence of dark adaptation and vitamin A values in blood serum.] *Roczn. Państwowego Zakł. Hig.*, 1955, 6, 47-54. Russian and English summaries.

In a study of 23 persons, aged from 24 to 67 years, some of whom complained of defective eyesight, a relationship was found in most of them between capacity for dark adaptation and the vitamin A value in the blood serum. It is suggested that the 2 tests supplement one another and that a combination of both tends to a more accurate estimation of vitamin A status. (From summary.)—J. S. Thomson.

GILLUM, H. L., MORGAN, A. F. and SAILER, F. Nutritional status of the aging. 5. Vitamin A and carotene. *J. Nutrition*, 1955, 55, 655-670. [California Agric. Exp. Stat., Univ. California, Berkeley.]

For other parts see Absts. 3986, 5444, and 5649, Vol. 25.

Carotene and vitamin A were estimated in blood from 514 healthy subjects over 50 years of age resident in San Mateo County, California. All were living in their own homes except 30 men dwelling in a county home. Physical examinations and 7-day dietary records were made. A small negative correlation was found between advancing age and the values for carotene and vitamin A. The mean values by decades, in μg . per cent., were for vitamin A 60, 54 and 50 for men, and 57, 57 and 50 for women. Corresponding carotene values were 119, 116 and 109 for men and 123, 127 and 113 for women. Differences

between the values for the sexes were not significant. About half the subjects, both male and female, had vitamin A values between 40 and 60 μg . per cent. Variation was wider in the carotene values, 62 per cent. of the subjects having values between 60 and 150 μg . per cent. From the records of dietary intake of pre-formed vitamin A and carotene the probable daily equivalents in terms of vitamin A were 2387 μg . for men and 1833 for women living in their own homes, and 1354 μg . for the men in the county home, which amounted, respectively, to 33, 27 and 21 μg . per kg. bodyweight. Of the total vitamin A potency, carotene represented 27, 29 and 18 per cent. in the 3 groups, respectively. About 11 per cent. of the men and 20 per cent. of the women in their own homes took vitamin A supplements more or less regularly and so raised their average total daily intakes from 10,640 to 11,470 I.U. for the men and from 8450 to 10,200 I.U. for the women. Thickening of the bulbar conjunctiva was seen in 94.1 per cent. of the subjects but was not correlated with the values for vitamin A in the serum, being no greater in those with the lower than with the higher values. The same was true for other changes in the skin and conjunctiva usually associated with deficiency of vitamin A. Thickening of the bulbar conjunctiva as a sign of vitamin A deficiency is considered to be of questionable value. I. M. Sharman.

HILLMAN, R. W., NERB, L. and HERTZ, H. The blood plasma vitamin A/carotene ratio and tocopherol concentration in relation to the metabolic state. *Amer. J. Digest. Dis.*, 1955, 22, 128-131. [Dept. Med., Brooklyn Hosp., N.Y.]

The B.M.R. and the concentration of vitamin A and carotene in the plasma were estimated in 25 patients with suspected thyroid dysfunction. Serum cholesterol was estimated in 24 and plasma tocopherol in 16 of them. The B.M.R. ranged from -23 to +50 per cent. In the plasma, per 100 ml., cholesterol ranged from 133 to 431 mg., vitamin A from 8 to 64 μg ., carotene from 41 to 310 μg ., and tocopherol from 0.1 to 0.7 mg. There appeared to be no relation between the value for vitamin A or carotene and the B.M.R. or between those values and that for cholesterol. There was also no relation between the plasma vitamin A: carotene ratio and serum cholesterol or B.M.R., between plasma tocopherol and plasma vitamin A or carotene or between plasma tocopherol and serum cholesterol or B.M.R. In 3 cases of hyperthyroidism in which serial estimations were made, the vitamin A and carotene values for 2 tended to vary inversely with the B.M.R. The plasma tocopherol level rose during control of the thyroid state in all 3 cases.—R. J. Ward.

M. and GANZIN, M. **Étude préliminaire de la prévention possible des carences protidiques par les lipides végétaux riches en carotène.** [Preliminary study of the possible prevention of protein deficiency by means of vegetable fats rich in carotene.] *Bull. Soc. Pathol. exot.*, 1954, **47**, 597-614. [Sect. Aliment. S.G.H.M.P., Hôp. Gén., Inst. Pasteur, Brazzaville.]

Results of several surveys are referred to, but special attention is given to one in the village of Koungoulou in the region of Sibiti in mid-Congo. The village is in the forest, far from the more industrialised regions of the Congo. It is inhabited by 2 tribes, the Bakota and Bayaka, each eating in its old-established, traditional way. Signs of deficiency were shown by only about 10 per cent. of the children. The children take part in the adult meals as soon as they can sit. The chief food is cooked bananas with palm oil and green-stuffs. Fish is eaten during 5 months of the year, and sometimes meat from the chase, but very little from domestic animals. Seventy-seven meals were inventoried and the mean daily content of nutrients was calculated per head for adults and children alike. The amount of food eaten appeared to be limited only by appetite. The daily intakes calculated were Cal. 2254, protein 27 g., fat 88 g. and carbohydrate 391 g. The amount of carotene supplied daily by palm oil alone was 32,000 µg. The mean blood values shown by the children for vitamin A and carotene were very high, 284 and 874 I.U. per cent., respectively. The authors believe that they have observed signs of vitamin A excess among the people consuming these large amounts of carotene. Although the protein intake was so low, the kwashiorkor syndrome was absent. It is considered that the optimum utilisation of the small amount of protein is promoted by the ample supply of palm oil. It is suggested that the action of carotene is mediated by the effect of vitamin A in depressing the activity of the thyroid gland.—E. M. Hume.

Vitamin D

- BILLE, B. S. V. **Non-rachitic craniotabes.** *Acta paediat.*, 1955, **44**, 185-202. [Child. Hosp., Sundsvall, Sweden.] French, German and Spanish summaries.

In the year 1 June 1951 to 31 May 1952, 1541 newborn infants in the Obstetric Clinic at Sundsvall were examined for the presence of craniotabes; of 1417 born spontaneously with cephalic presentation, 228 had congenital craniotabes. It was possible to follow 274 of the children for 1 or 2 years; 47 of them had congenital craniotabes and 61 developed it in the first year. None of them had any sign of rickets. Analysis of factors such as sex, birthweight, birth order, presentation, and posture in *utero*, led the author to the conclusion that craniotabes is not a sign of rickets, but is induced by pressure on the skull, from the pelvic bones in *utero*, or from lying in the horizontal position after birth.—E. M. Hume.

- JESSERER, H. **Ueber die Wirkungsunterschiede verschiedener Lösungen von Vitamin D₂ und D₃ bei peroraler, intravenöser und intramuskulärer Zufuhr.** [Differing activity of various solutions of vitamin D₂ and D₃ given orally and by intravenous and intramuscular injection.] *Wien. klin. Wochenschr.*, 1955, **67**, 49-53. [I. Med. Klin., Univ. Vienna.]

Available preparations of vitamin D₂, vitamin D₃ and dihydrotachysterol are listed. The author summarises his experience over 8 years of 260 patients with parathyroid insufficiency.

Given orally, the 3 substances were of equal potency for raising the blood Ca value, and the medium, whether oil, alcohol or water, was unimportant if the patient's capacity for absorption was unimpaired. A single oral dose of from 90 to 150 mg. of any of the 3 could safely be given to combat tetany, but the same amount given in smaller doses over several days was much more likely to induce hypercalcaemia. For maintenance the oral dose recommended is 2 or 3 mg. daily or from 15 to 20 mg. a week.

Given intravenously the 3 substances had a more rapid, powerful and lasting effect on the blood Ca value than when given orally, and vitamin D₂ was more active than the other 2. The dose should be only about one-third of that given orally.

Given by intramuscular injection in oil solution, the 3 substances were much less active, vitamin D₂ being relatively more active than the other 2. In a water preparation vitamin D₂ and vitamin D₃ were almost as active as when given orally. No aqueous preparation of dihydrotachysterol was available.

To test the rate of absorption of 4 different oils given by intramuscular injection, Sudan III was dissolved in them, and they were injected into groups of 3 rats, and the degree of staining of the body fat was recorded for up to 6 days. Cod liver oil was rapidly absorbed, olive oil more slowly, arachis oil very little and paraffin oil not at all.

FISHMAN, W. H. Methionine-induced amino-aciduria in vitamin D resistant rickets. *Metabolism*, 1955, 4, 107-109. [Cancer Res. Unit, Med. Sch., Tufts Coll., Boston, Mass.]

Two children, 6 years of age, were admitted to hospital with a diagnosis of vitamin-D-resistant rickets. They were given daily for 10 days 4.2 g. methionine in 3 divided doses. In the urine, free amino-acids were estimated by formol titration, aliphatic hydroxyamino-acids by the periodate method, and a number of individual amino-acids microbiologically. After treatment with methionine the total amounts of hydroxyamino-acids and of free amino-acids were greatly increased compared with the amounts in control periods of 12 days before and after administration of methionine. Methionine was the only amino-acid tested of which the amount was greater in the period of treatment than in the subsequent control period. [In the Table figures are not given for individual amino-acids in the control period before treatment, and it is not clear whether no test was made or none of those amino-acids was found.]

FYFE, W. M. Rheumatoid arthritis in childhood. *Glasgow Med. J.*, 1955, 36, 103-110. [Dept. Child Health, Univ. Glasgow.]

In a follow-up study of some 50 children with rheumatoid arthritis it is reported that 7 were treated in the initial attack or in relapse with 100,000 "units" of vitamin D₂ daily for periods ranging for from 10 days to 5 years. In 6 of them the disease has become quiescent and 5 have recovered completely. Nevertheless, only a guarded claim is made for the treatment, in view of the variable course and prognosis of rheumatoid arthritis.—W. M. Deans.

5591

JONKIS, J. H. P. Het toevoegen van vitamine D aan voedingsmiddelen. [The addition of vitamin D to foodstuffs.] *Voeding*, 1955, 16, 518-523. [Algem. Ziekenhuis, Groningen.]

The general problem of obtaining vitamin D from food and from exposure to the sun's rays is discussed with reference to the need for its addition to children's diets in Holland. The difficulties of adding vitamin D to milk are considered too great for it to serve as vehicle. Margarine with 20 or 40 I.U. added per g. is suggested as the best way to provide vitamin D in all diets. The prophylactic administration of a single large dose to children at about 18 months of age is suggested as a precaution against rickets.—A. M. Copping.

5592

TE RIELE, J. H. Margarine en rachitisbestrijding. [Margarine and prevention of rickets.] *Voeding*, 1955, 16, 188-195. English and French summaries.

Dols and Sevenster concluded in a report, *Productie en bestemming van melk in Nederland*, Rotterdam, 1950 that it was improbable for the nutritional value of margarine in a properly varied diet to be inferior to that of butter, if the margarine contained the same amount of vitamins as butter. In the same year the Milk Utilisation Committee of the Agricultural Institute reported that proof had not yet been given of the equal nutritive value of butter and margarine. The controversy is still of importance, for consumption of margarine in the Netherlands is at present 3

times that before the war, being about 50 g. per head daily. The high price of butter is undoubtedly a contributing reason, but the margarine is of good quality, maintained in spite of competition for markets by reduction of price. Since such large quantities of margarine are eaten, the addition of vitamins could be used to prevent rickets, the only remaining deficiency disease of children in the Netherlands. The number of margarine factories in the Netherlands is small, so supervision would be easy. It is suggested that solutions of vitamins A and D in standard proportions might be made by chemical factories and delivered to the margarine factories in sealed bottles. A relatively simple test for vitamin A would then serve to show the content of vitamin D. The addition of 40 I.U. vitamin D₂ and 40 I.U. vitamin A per g. margarine is advocated.

M. Eddison.

5593

THIERS, H. De l'intérêt biologique et thérapeutique du stigmastérol. [Biological and therapeutic importance of stigmastérol.] *Presse méd.*, 1955, 63, 820-821. [Lyons.]

In this general article the work on stigmastérol as an anti-stiffness factor for guineapigs is summarised (see Abst. 1356, and Titles 826 and 1357, Vol. 21). The substance is a plant sterol, long known. Its use, especially with ascorbic acid, is strongly advocated for the treatment in human beings of scleroderma, inflammatory cellulitis after phlebitis, neuritis of vertebral or muscular origin, coxarthroses and some forms of spondylitis. It is thought to act directly and not as a precursor of vitamin D. It is transformed by ultraviolet irradiation into a form of vitamin D which is active in man when given for long periods.

L. Wills.

5594

SARTORI, E. Die klinische Bedeutung der Calciumfraktionen der Körpersäfte. [The clinical importance of the calcium fractions in the body fluids.] *Helv. paediat. Acta*, 1955, 10, 104-110. [Kinderklin., Univ. Padua.]

Ca in body fluids was estimated in 3 fractions, Caa representing the ionised fraction biologically active for frog's heart, Cab the non-ionised ultrafiltrable fraction and Cac the colloidal non-ultrafiltrable Ca. Over 1000 estimations were made, mostly in serum and cerebrospinal fluid (CSF) of healthy and sick children.

The values for total Ca and for the 3 fractions [presumably in mg. per 100 ml.] in healthy children were: for serum 9.96, 4.52 ± 0.27 , 1.13 ± 0.40 and 4.28 ± 0.58 , and for CSF 5.47, 4.73 ± 0.22 , 0.38 ± 0.25 and 0.36 ± 0.18 . The difference in Cac is highly significant.

The values for 20 healthy infants were compared with those for 20 infants with manifest rachito-

genic tetany, 6 with latent rachitogenic tetany, 2 with so-called idiopathic hypoparathyroid tetany and 2 with tetany of renal origin. In all the infants with tetany the greatest fall in serum Ca was in fraction Caa; in manifest rachitogenic tetany the Caa fraction was lower than in latent tetany, and this was accompanied by a significant fall in Cac. In hypoparathyroid tetany the Caa fraction was very low and a significant rise in Cab occurred.

Administration of vitamin D₂ with A.T. 10 to 9 infants with rickets caused in 7 an increase in serum Caa and usually a clinical improvement, but the effect on the serum Caa was less than that produced by vitamin D₂ alone in 6 normal children. In CSF the fall in Caa in tetany was less than that in serum.

Clinically the level of Caa in serum can be used to differentiate tetany from generalised convulsions (see next Abst.).—D. Duncan.

5595

SARTORI, E. Die Calciumtoxikose als klinisch-biochemischer Zustand. [Calcium poisoning as a clinical and biochemical condition.] *Helv. paediat. Acta*, 1955, 10, 123-130. [Kinderklin., Univ. Padua.]

The serum Ca was studied in 5 infants aged from 3½ to 11 months, with vitamin D intoxication. Compared with normal infants they had high total serum Ca and increases probably in all the fractions (see preceding Abst.), but especially in Caa. The mean values, in mg. per cent., for normal and affected infants, and the ranges for the latter, were: total Ca 9.62, 14.09, 10.32 to 16.75; Caa 4.31, 7.38, 5.68 to 9.46; Cab 1.06, 1.33, 1.06 to 2.18; Cac 4.25, 5.38, 2.64 to 8.17. The rise in Caa reflected the severity of the clinical condition.

The rise in Caa is the direct result of administration of vitamin D, and smaller increases were seen in children 3 to 6 years old in the 48 hr. after they received 25 mg. vitamin D.

In 2 infants there was a reduction in thiocyanate space during vitamin D intoxication. The role of the high concentration of Ca ions in the tissues in the production of the clinical syndrome is discussed. It is suggested that treatment should include slow intravenous infusion of sodium citrate in Ca-free physiological solution.—D. Duncan.

Vitamin E

5596

BECKMANN, R. and FEGELER, F. Serum-Tocopherol-Studien nach peroraler Applikation von dl- α -Tocopherolacetat. [Serum tocopherol studies after oral administration of dl- α -tocopheryl acetate.] *Klin. Wochenschr.*, 1955, 33, 76-82. [Kinderklin., Westfälische Wilhelms Univ., Münster.]

Previous reports on the tocopherol content of human serum are reviewed and summarised. When tocopherol was estimated by the $\alpha\alpha'$ -dipyridyl and ferric chloride method in 105 subjects, values ranging from 1200 to 2000, average 1500, $\mu\text{g. per } 100 \text{ ml. serum}$ were obtained. A single dose of from 100 to 600 mg. tocopheryl acetate as tablets, or as an aqueous dispersion given orally, or as an injection of pure *dl*- α -tocopherol, caused a rise in the serum tocopherol. The value reached the maximum about 4 hr. after the dose and returned to normal in 24 hr. except when very large doses of 200 mg. were given. An oily solution of tocopherol by cutaneous application had no effect on the serum value; given by mouth or injection it was absorbed equally rapidly into the bloodstream.—A. M. Copping.

RÄHÄ, N. Hemolysis of human blood caused by oxygen and its prevention with vitamin E: preliminary report. *Acta paediat.*, 1955, 44, 128-131. [Child Clin., Helsinki.] French, German and Spanish summaries.

Specimens of adult human blood were treated with heparin and incubated in bottles in which the empty space was filled with pure oxygen. The degree of haemolysis, estimated by centrifuging and measuring the red colour of the plasma, increased with the time and temperature of incubation. When different concentrations of oxygen were used the degree of haemolysis after 24 hours' incubation at 37° C. was roughly proportional to the concentration of oxygen. Haemolysis was much reduced if the subjects had been given 100 mg. vitamin E 24 hr. previously. In preliminary experiments on umbilical blood, marked haemolysis occurred even at low concentrations of oxygen, and even when the mother had been given vitamin E before delivery.—T. Moore.

5599

BISHOP, C., RAND, R. and TALBOTT, J. H. Rate of conversion of isotopic glycine to uric acid in the normal and gouty human and how this is affected by vitamin E and folic acid. *Metabolism*, 1955, 4, 174-182. [Chronic Dis. Res. Inst., Dept. Med., Buffalo, N.Y.]

One normal subject and 2 gouty subjects, one with tophi and one without, were given from 1.5 to 2 g. isotopic glycine, and uric acid excretion

was estimated by the isotope dilution technique. From the isotope concentration of the urinary uric acid after it had reached its maximum, a first-order rate constant was calculated which was considered to represent the turnover rate of a precursor of uric acid. Short term therapy with folic acid and vitamin E was given to the gouty subject without tophi; it did not affect the rate constant but after intensive and prolonged treatment with vitamin E the constant reverted to that found in the normal subject.—R. J. Ward.

BUTLER, E. B. and McKNIGHT, E. Vitamin E in the treatment of primary dysmenorrhoea. *Lancet*, 1955, 268, 844-847. [Dept. Obstet. Gynaecol., Cardiff Royal Infirmary.]

A group of 100 women with a history of painful or incapacitating dysmenorrhoea was selected from students living in university hostels. Half of them, chosen at random, were given 50 mg. α -tocopherol, three times daily for 14 days, starting 10 days before menstruation was expected. The others received a dummy. Neither the women nor the investigators knew which treatment was received. The effect of the treatment was usually studied over 3 menstruations. The number of women who reported less pain or incapacity during the 3 menstruations, compared with their previous experience, was much greater among those given tocopherol than among those given the dummy.

GALLETTI, F., GELLI, G. and GIUNGI, F. Azione della vitamina E sul processo di coagulazione del sangue in malati di tubercolosi polmonare. [Effect of vitamin E on blood coagulation in patients with pulmonary tuberculosis.] *Acta vitaminol.*, 1955, 9, 71-75. [Inst. Clin. Med. Gen., Univ. Bologna.] French, English, German and Spanish summaries.

Tests were made on the coagulatory factors in the blood and on vascular fragility in 10 healthy subjects and 28 patients with pulmonary tuberculosis, beforehand, and on 5 successive days 2 hr. after intramuscular injection of 100 mg. α -tocopheryl acetate. In the healthy subjects the blood tests and capillary fragility were normal, and were not affected by treatment with vitamin E. In the tuberculous subjects coagulation time, bleeding time, retraction of the clot and vascular fragility were normal or almost normal and were

not affected by treatment with vitamin E, but in 20 of the patients there was prolongation of the prothrombin time and time of Howell, both of which returned to normal after administration of vitamin E.—E. M. Hume.

CRUMP, J. and TULLY, R. The use of partial vitamin supplements in the treatment of growth failure in children. *J. Pediat.*, 1955, 46, 671-681. [Women's Med. Coll., Philadelphia, Pa.]

Fifty children with malnutrition and anorexia from chronic illness were treated at home for periods of up to 2 years with daily oral doses of 25 µg. vitamin B₁₂ and 10 mg. vitamin B₁. Clinically the children appeared to benefit; there was generally an increase in appetite with a resulting increase in rate of growth and gain of weight. Wetzel Grid charts were prepared for 32 of the children; they showed significant positive shifts in 16 of 18 children whose charts showed a previous failure of growth, but no significant change in the 14 children with no such indication. The results were confirmed in a further analysis by the Tuxford method.—L. Wills.

HICKIS, G. W. Pellagra in an English child. *Arch. Dis. Childhood*, 1955, 30, 195-196. [Odstock Hosp., Salisbury.]

A girl aged 4 years and 9 months was admitted to hospital suffering from pellagra. Her appetite was poor and her nicotinic acid intake was estimated to have been only 1 mg. daily. She had refused to take cereals, meat or green vegetables since the age of 1 year. Some improvement resulted from treatment with nicotinamide, but stimulation of appetite with insulin was necessary for full recovery.—F. C. Aitken.

HORWITT, M. K. Niacin-tryptophan relationships in the development of pellagra. *Amer. J. Clin. Nutr.*, 1955, 3, 244-245. [Biochem. Res. Lab., Elgin State Hosp., Ill.]

Thirty patients received for 2 years a basal diet providing daily 2300 Cal., 5.8 mg. nicotinic acid and 265 mg. tryptophan daily, some without supplement, and others with daily supplements of 10 mg. nicotinic acid or 100 mg. tryptophan. By comparing the urinary excretion of N²-methyl-nicotinamide with the intake of nicotinic acid precursors in the 3 groups, the relative values of tryptophan and nicotinic acid for producing N²-methylnicotinamide were found to be 1 and 60. If, therefore, 60 mg. tryptophan is taken as the equivalent of 1 mg. nicotinic acid, the total nicotinic acid equivalent of the basal diet, which contained little maize and produced no pellagra, was 4.43 mg. per 1000 Cal. Similar calculations for the pellagra-producing diets of Goldberger et al. (*U.S. Pub. Health Rep.*, 1915, 30, 3336) and of

N.A. and R., October 1955

Goldsmith *et al.* (Abst. 856, Vol. 23) gave values of 3.90 and 3.93 mg., and for the latters' wheat diet, on which pellagra did not develop, 4.77 mg. The results are considered to provide evidence that pellagra will develop on diets with a total nicotinic acid equivalent of 3.9 mg. per 1000 Cal., but not with one of 4.7.

It is suggested that if maize forms a "sufficiently large proportion of a diet, pellagra will not develop", as happens with the Guatemalan Indians, who consume about 500 g. maize daily (Abst. 240, Vol. 24). If, however, about half the maize in that diet was replaced by foods poor in protein and rich in carbohydrate, such as sweet potatoes or maize syrup, the diet would cause pellagra if consumed for 4 months or longer.

It is concluded that there is little justification for a belief in the existence of a toxic substance in maize.—H. Chick.

CHANG, Y. O., LAURSEN, T. J. S. and KIRK, J. E.

The total nicotinic acid and pyridine nucleotide content of human aortic tissue. *J. Gerontol.*, 1955, 10, 165-169. [Div. Gerontol., Sch. Med., Washington Univ., St. Louis, Mo.]

The average value in $\mu\text{g. per g.}$ fresh tissue for total nicotinic acid is 65, and for pyridine nucleotides in 39 samples of aortic tissue from human subjects aged between 2 weeks and 82 years was, respectively, 19.2 with range from 10.2 to 33.0, and 25.8 with range from 4.9 to 51.8. Nicotinic acid content tended to decrease as age increased. Since pyridine nucleotides were destroyed rapidly during storage at 37° C. the values obtained must have been considerably lower than those prevailing *in vivo*.—A. Hepburn.

5613

IRINODA, K. and SATO, S. Contribution to the ocular manifestation of riboflavin deficiency. *Tohoku J. Exp. Med.*, 1954, 61, 93-104. [Ophthalmol. Clin., Fac. Med., Hirosaki Univ.]

Clinical observations on patients with a disease due to malnutrition, so-called "Shibi-Gattehaki" disease, which is prevalent in Japan in Aomori Province, showed the presence of degenerative and inflammatory changes in the cornea and retina associated with angular stomatitis, glossitis and proctitis, suggestive of riboflavin deficiency. Administration of riboflavin caused improvement in the eye lesions.

Rabbits given a diet deficient in riboflavin developed superficial corneal opacity, corneal vascularisation, oedema of the vacuoles in the corneal epithelium, and degeneration of the retinal ganglion cells. Ocular and other signs of deficiency were cured by riboflavin.

Vol. 25, No. 4

The nature of the eye changes in riboflavin deficiency is discussed with particular reference to the function of the vitamin in oxidative enzyme systems.—A. M. Copping.

SCHAUS, R., KIRK, J. E. and LAURSEN, T. J. S.

The riboflavin content of human aortic tissue. *J. Gerontol.*, 1955, 10, 170-177. [Div. Gerontol., Sch. Med., Washington Univ., St. Louis, Mo.]

The average values for free riboflavin together with flavin mononucleotide, for flavin adenine dinucleotide and for total riboflavin in 100 samples of aortic tissue from human subjects aged between 4 weeks and 83 years were 0.40, 0.76 and 1.16 $\mu\text{g. per g.}$ fresh tissue. The content of total riboflavin tended to fall as age increased. Corresponding values for 5 dogs were 0.26, 2.31 and 2.57. Incubation of the samples at 38° C. caused a decrease in flavin adenine dinucleotide and an increase in free riboflavin which suggested the existence of some enzyme activity.—A. Hepburn.

5615

MAENGWYN-DAVIES, G. D., BECKER, B., ROSEN, D. A. and FRIEDENWALD, J. S. A comparison of acetylating capacity of normals and diabetics with and without retinopathy. *Bull. Johns Hopkins Hosp.*, 1955, 96, 150-153. [Wilmer Ophthalmol. Inst., Sch. Med., Johns Hopkins Univ., Baltimore, Md.]

The acetylating capacity of 43 normal subjects and 33 diabetic patients was tested by measuring the urinary excretion of free and acetylated sulphamide in response to a dose of 1 g. sulphadiazine. During 24 hr. after the dose diabetic patients acetylated a significantly larger proportion of the dose than normal subjects; no difference was found between 13 diabetic patients with retinopathy and 20 with no retinal change. The rate of acetylation decreased with age and when correction for age was made between the normal and diabetic groups no significant difference in acetylating capacity was apparent. It was, therefore, concluded that deficiency of pantothenic acid or more specifically of coenzyme A was not characteristic of diabetes.—A. M. Copping.

BUCELLATO, G. Sui valori della piridossina nel siero di sangue e nell'urina di soggetti sottoposti ad una iniezione di piridossina sola od associata a manganese colloidale. [Values for pyridoxine in the blood serum and urine in subjects given an injection of pyridoxine alone or with colloidal manganese.] Possibile azione attivante sul ricambio glucidico di un composto piridossina-manganese formantesi *in vitro*. [Possible action in activating carbohydrate metabolism of a compound of pyridoxine and manganese formed *in vitro*.] *Bol. Soc. ital. Biol. sper.*, 1953, 29, 1541-1542; 1542-1544. [Clin. Dermatol., Univ. Palermo.]

It has been observed (*Dermatologia*, 1953, 4, 234) that the beneficial effect on psoriasis of pyridoxine and colloidal Mn was greater when the two were given together than when either was given separately. The formation of a salt between pyridoxine and Mn was suggested. Pyridoxine was estimated by a colorimetric method, based on measuring the amount of phenol, in the blood and urine of 6 patients with psoriasis, given intravenously 200 mg. pyridoxine alone, or with intramuscular injection of 2 mg. Mn 12 hr. before, and 2 mg. at the same time as, the injection of pyridoxine. When pyridoxine was given alone its concentration in both blood and urine remained high for from 4 to 8 hr. and then declined slowly. When Mn was given as well the concentration of pyridoxine rose only slowly, being highest after from 8 to 12 hr. It was suggested that the compound with Mn was formed at once and that pyridoxine was not estimated by the method as long as it remained in combination.

The injection materials were mixed *in vitro*, and the colour gradually changed from brown to yellow. The change was accelerated by a rise of temperature to 37° and 55°C. or by addition of fragments of liver or spleen tissue. The formation of a compound is conjectured and a structural formula is given showing how it could take place.

An action on carbohydrate metabolism is suggested. E. M. Hume.

BLEILER, R. E., JOHNSON, D. and PARSONS, H. T. Metabolism of folic acid and citrovorum factor by human subjects. *J. Nutrition*, 1955, 56, 163-171. [Dept. Foods Nutrit., Sch. Home Econ., Univ. Wisconsin, Madison.]

Urinary excretion of folic acid and citrovorum factor was measured by microbiological methods in the urine of 15 subjects having daily in their diet 100 mg. ascorbic acid with and without a dose of 1 or 5 mg. folic acid. A similar study on 22 consecutive days was made with 4 young women having a restricted diet containing only 25 mg. ascorbic acid daily. In all the subjects the proportion of citrovorum factor to folic acid excreted was about 1 : 4 before folic acid was administered. As soon as folic acid was given there was a great increase in excretion of folic acid but not of citrovorum factor, except when an excessive dose of 750 mg. ascorbic acid was given simultaneously. The possible formation of folic acid metabolites other than citrovorum factor is discussed.

SUURALA, M. Gastric lesion in some megaloblastic anaemias: with special reference to the mucosal lesion in pernicious tapeworm anaemia. *Acta med. scand.*, 1955, 151, Suppl. 299, pp. 47. [2. Med. Clin., Univ. Helsinki.]

A study was made of 88 cases of megaloblastic anaemia, including 58 untreated cases of pernicious tapeworm anaemia and 17 untreated and 5 relapsed cases of Addisonian pernicious anaemia; 66 tapeworm carriers and 45 cases of idiopathic

atrophic gastritis served as controls. The cases were classified according to age; the pernicious tapeworm anaemia cases and the worm carriers were comparable for each age group. The majority were over 40 years of age. Gastroscopic examination of the body of the stomach showed atrophic changes, partial or total, in the mucosa of all the patients with Addisonian pernicious anaemia and of 50 out of 54 of those with pernicious tapeworm anaemia, but of only 23 of 63 tapeworm carriers, in whom the atrophy was never total. In all age groups the incidence of atrophy was significantly less in the worm carriers. The type of atrophy was similar in all cases.

There was no correlation between the gastroscopic appearance and the blood findings or the response to treatment or the neurological findings, but there was some correlation between the degree of atrophy and the lingual changes. Histological examination of biopsy material showed that atrophy, generally partial, was present in specimens from 30 out of 35 cases of pernicious tapeworm anaemia and in 11 out of 50 specimens from worm carriers; in 22 cases of pernicious anaemia atrophy was total in 18 and partial in 4. In pernicious tapeworm anaemia there was no correlation between the histological changes and the blood and neurological findings. Moderate or severe inflammatory cell infiltration of the mucosa was present in 25 per cent. of the patients with Addisonian pernicious anaemia, in 60 per cent. of those with pernicious tapeworm anaemia and in 75 per cent. of those with atrophic gastritis. Superficial inflammation also was most frequent in the gastritis patients; in pernicious tapeworm anaemia it occurred most frequently in patients with only a slight degree of atrophy, which suggested that the initial lesion was often inflammatory. In pernicious tapeworm anaemia there was a fair degree of correlation between the presence of atrophic changes and the presence of achlorhydria, but in atrophic gastritis with a comparable degree of mucosal atrophy the incidence of achlorhydria was significantly lower than in pernicious tapeworm anaemia, and the correlation was not so good. Achlorhydria was found in some cases of pernicious tapeworm anaemia with normal gastric mucosa; it is suggested that some factor other than mucosal atrophy plays a part in the production of achlorhydria in these cases.

In an interesting discussion it is suggested that in some if not all cases of pernicious tapeworm anaemia the mucosal atrophy results from a deficiency state produced by the infestation, and may develop as the disease progresses; follow-up studies are in progress to investigate whether the atrophic changes can be reversed by deworming and cure of the anaemia and the hypothetical deficiency state.—L. Wills.

MONTO, R. W. and HOWELL, J. T. Urinary vitamin B₁₂ activity following intranasal administration. *J. Lab. Clin. Med.*, 1955, **45**, 474-477. [Div. Haematol., Henry Ford Hosp., Detroit 2, Mich.]

Two normal subjects were given, by nasal instillation, 200, 100 and 50 μ g. crystalline vitamin B₁₂ in 0.5 ml. saline, each dose on a separate day; 200 or 150 μ g. crystalline vitamin B₁₂ was placed directly on the nasal mucosa of 2 patients with pernicious anaemia in relapse. Significant vitamin B₁₂ activity was detected in the urine of all. The 2 anaemic patients responded well to the treatment and chronic disease of the nasal mucous membrane in one of them did not apparently impede absorption. (See also Title 3497, Vol. 23; Abst. 5215, Vol. 24).—F. C. Aitken.

CALLENDER, S. T. and EVANS, J. R. The urinary excretion of labelled vitamin B₁₂. *Clin. Sci.*, 1955, **14**, 295-302. [Nuffield Dept. Clin. Med., Radcliffe Infirmary, Oxford.]

The reliability of Schilling's test, which measures the excretion of radio-active vitamin B₁₂ when a small oral dose of it is followed by a large parenteral dose of unlabelled vitamin B₁₂ (Abst. 3675, Vol. 24), was assessed by comparing urinary and faecal excretion of the radio-active vitamin B₁₂. Tests were made on 26 normal subjects, 38 patients with pernicious anaemia and 33 others with infections, steatorrhoea, and other diseases, and after gastrectomy. About one-third of an

oral dose of radio-active vitamin B₁₂ was excreted in the urine by normal subjects in response to an injection of 1000 μ g. of unlabelled vitamin and very small amounts by patients with pernicious anaemia. Administration of intrinsic factor to patients with pernicious anaemia increased the amount of radio-active vitamin B₁₂ appearing in the urine. In the faeces, the same normal subjects excreted about one-third of the radio-active dose given orally, but patients with pernicious anaemia excreted about 90 per cent. of it. The results agreed well with those for excretion in the urine. Of the other groups, only patients with steatorrhoea behaved like those with pernicious anaemia in the amount of vitamin B₁₂ excreted in the faeces after an oral dose. The advantages and simplicity of the urinary excretion test are emphasised.—A. M. Copping.

RALLI, E. P., BARBOSA, X., BECK, E. M. and LAKEN, B. Blood sugar and sulphhydryl levels in diabetic patients before and during vitamin

B₁₂ therapy. *Proc. Soc. Exp. Biol. Med.*, 1955, **88**, 646-649. [Dept. Med., Coll. Med., New York Univ.-Bellevue Med. Centre.]

Plasma values for sulphhydryl were estimated by an amperometric method, blood sugar by Somogyi's method, and serum protein by paper electrophoresis, in blood from 27 patients with diabetes mellitus, 21 normal subjects and 10 patients with cirrhosis of the liver. Intramuscular injections of 1 mg. vitamin B₁₂ were given daily to 16 of the diabetic patients for 6 to 18 months. Values for sulphhydryl compounds were low in patients with cirrhosis of the liver, but no differences were observed in the other patients, and no relation was established between the sulphhydryl and blood sugar values. Treatment with vitamin B₁₂ had no effect on the concentration of sulphhydryl compounds in diabetic patients.—A. M. Copping.

JANOUSEK, S., KROULÍKOVÁ, J. and MALÍŠ, F. Polarografická studie o autoproteolytické trávicí schopnosti okyseleného sera a její změně u perniciosní anemie. [Polarographic study of the autoproteolytic, digestive capacity of acidified human serum and its modification in pernicious anaemia.] *Čas. Lék. čes.*, 1955, **94**, 83-89. [Prague.] Russian and English summaries.

A simple polarographic method for estimating autoproteolytic enzymic activity in blood serum is described. Serum from 36 patients with pernicious anaemia had lower activity than that from 97 other patients. Analysis was made of the activity curves of serum from a healthy individual and a patient with pernicious anaemia. The normal serum had 3 optimum pH ranges for proteolytic activity, between 2.0 and 3.0, between 3.0 and 4.0, and between 5.0 and 7.0. In the serum of the patient with pernicious anaemia, the first was lacking, the second was present and the activity was greater than in the normal serum, and the third was present and maintained. The activity lacking was that of pepsin quality. (From summary).—E. M. Hume.

5641

WILD, C., REYMOND, C. and VANNOTTI, A. Vitamine B₁₂ et métabolisme protidique. [Vitamin B₁₂ and protein metabolism.] *Schweiz. med. Wochenschr.*, 1955, **85**, 145-151. [Clin. Méd., Univ. Lausanne.]

The effect of vitamin B₁₂ on the absorption and utilisation of amino-acids was studied by following the amino-acid N values in the blood at half-hour intervals after an oral dose of 10 g. of a hydrolysate of casein and lactalbumin. In 14 adult subjects of both sexes with no recognisable lesion

of the digestive tract, the blood amino-acid N values after the test dose rose steeply by a mean maximum amount of 1.61 mg. per 100 ml. after half an hour, and fell gradually to a value 0.37 above the initial value after 2 hr. When, in another test, 1000 µg. vitamin B₁₂ were given intravenously immediately before the test dose, the initial mean rise of 0.81 mg. per 100 ml. was significantly lower than in the first test and the later values were significantly lower than the initial value.

To investigate the mode of action of the vitamin, the blood amino-acid N value was estimated in 11 subjects after 1 ml. of normal saline or 1000 µg. vitamin B₁₂ had been given intravenously; after the saline the blood value did not alter significantly, but 2 hr. after the vitamin the value had fallen significantly compared with the value after saline. From the results it was concluded that the effect of vitamin B₁₂ on the amino-acid N value was due not to slowing of absorption but to improvement in utilisation.

Since the liver is considered to be the principal site of polypeptide formation, further studies were made on 14 patients suffering from cirrhosis or infective hepatitis with proven liver failure. The mean blood values after the test dose of protein hydrolysate were slightly but significantly higher than in normal subjects, and vitamin B₁₂ had no effect on the height of the rise. As alternative explanations of the results, it is suggested that the vitamin must be changed in the liver before its enzymic action can manifest itself, or that in a diseased liver there is failure in polypeptide synthesis at the point where it is stimulated by vitamin B₁₂. The effect of vitamin B₁₂ on the amino-acid N curve is suggested as a test of liver function; the suggestion is made because in a patient with hypoproteinaemia of unknown origin the diagnosis of liver disease was made on that ground and later confirmed, though at the time all the usual tests of liver function were negative.

In pernicious anaemia the test curve was very flat; vitamin B₁₂ given by mouth with intrinsic factor caused a marked increase in absorption, and the vitamin given alone intravenously produced a further marked increase in utilisation. In patients with *anorexia nervosa* the test showed that absorption of amino-acids was normal but utilisation delayed; with vitamin B₁₂ there was a slow stimulation of utilisation.

In conclusion it is pointed out that previous work showed that in patients with poor absorption of the amino-acids the vitamin B complex alone stimulates absorption and restores the curve to normal. Vitamin B₁₂, on the other hand, stimulates utilisation of amino-acid N so that the normal curve is depressed. The literature is reviewed.

KARLIN, R. **Influence de l'administration de la vitamine B₁₂ par voie buccale ou parentérale, sur la teneur en cette vitamine du lait humain.** [Effect of oral or parenteral administration of vitamin B₁₂ on the amount in human milk.] *Bull. Soc. Chim. biol.*, 1954, **36**, 1665-1669. [Inst. Pasteur, Lyons.]

An oral dose of 100 µg. vitamin B₁₂ given for 6 days to 5 lactating women caused a small increase in the vitamin B₁₂ content of the milk within 24 hr. of the first dose. The rise disappeared in a day or two after the dose was withdrawn. The

same dose combined with 20 mg. cobalt had a greater effect on the vitamin B₁₂ content of the milk, but there was no prolongation of the effect after withdrawal. A single intramuscular injection of 100 or 400 µg. vitamin B₁₂ produced a great increase in the vitamin B₁₂ content of the milk; the value reached a maximum in about 12 hr. and remained high for from 48 to 72 hr.

PERITI, P. **Azione delle forti dosi di vitamina B₁₂ per via orale nella dispepsia da grassi in bambini allattati al seno materno.** [Action of large doses of vitamin B₁₂ given orally in the fat dyspepsia of breast-fed babies.] *Bol. Soc. ital. Biol. sper.*, 1953, **29**, 1391-1392. [Ambulatorio Pediat., Sez. Pontassieve Ist. Naz. Assicurazioni Malattie, Florence.]

Breast-fed infants aged from 20 to 100 days, suffering from fat dyspepsia with a cutaneous eruption, were given orally from 50 to 100 µg. vitamin B₁₂ daily, from which, in conjunction with wider spacing of the feeds, they derived great benefit. The vitamin was given in amounts of from 12.5 to 25 µg. in a spoonful of skimmed milk just before the feeds. The treatment was continued until a cereal was included in the diet.

AGUIRRE, F. and SCRIMSHAW, N. S. (with Muñoz, J. A. and CABEZAS, A.) **The effect of supplements of animal and vegetable protein, vitamin B₁₂, and aureomycin on hematological values in Central American school children.** *Amer. J. Clin. Nutr.*, 1955, **3**, 225-229. [Inst. Nutrit. Central America and Panama, Guatemala.]

Haematological studies were made on 426 children in 2 urban and 3 rural schools in El Salvador and 4 rural schools in Guatemala. The average values in the respective groups of schools were 4.31, 4.05 and 4.40 million red cells per c.mm., and 12.0, 11.4 and 13.3 g. Hb per 100 ml. The incidence of anaemia assessed by these criteria was high and all the cases were of macrocytic type. The quality of the protein in most diets was poor but provision for 5 months in El Salvador of a school lunch rich in animal protein produced no improvement in the blood picture. Other lunch programmes providing increases in animal and vegetable protein for periods up to two years had no effect on the red cell count or Hb value. Oral administration of 20 µg. vitamin B₁₂ or 50 mg. aureomycin in addition to a high-protein lunch had no significant effect. The incidence of hookworm infestation was high and was little improved by treatment, opportunities for re-infestation being very numerous.—A. M. Copping.

MORGAN, A. F., GILLUM, H. L. and WILLIAMS, R. I.
Nutritional status of the aging. 3. Serum ascorbic acid and intake. *J. Nutrition*, 1955, 55, 431-448. [California Agric. Exp. Stat., Univ. California, Berkeley.]

For other parts see Absts. 3986, 5444, 5576, Vol. 25.

Ascorbic acid was estimated in the serum from 569 healthy men and women who were over 50 years of age and living in their own homes, except for 44 men who were over 60 years and living in a county home. At all ages women had higher values than the men, the mean values being 1.07 and 0.83 mg. per cent. The maximum for both sexes was in the age group for 60 to 64 years with 1.21 and 0.94 mg. per cent. The women had a smaller daily intake of ascorbic acid at all ages than the men with mean values of 86 and 99 mg.; the maximum intake was in the age group from 60 to 64 years, the values being 91 and 136 mg. Expressed as mg. per kg. bodyweight the intakes of 1.28 and 1.36 mg. did not differ significantly. Vitamin supplements which might have contained ascorbic acid were taken more or less regularly by 15 per cent. of the men and 18 per cent. of the women; the supplements were not included in calculating intake. The mean value for the men in the county home was 0.27 mg. per cent. in the serum, and the mean total daily intake was 40 mg.

A direct correlation was found between the serum value and the intake of ascorbic acid. When the subjects were divided into 4 income groups the mean serum ascorbic acid value increased progressively from the lowest to the highest.

Of 551 subjects examined, 219 had no teeth, 94 had some degree of gingivitis, and 238 had teeth and healthy gums. The mouths were healthier in those with the higher serum values.

A. Hepburn.

KALT, F. Der Vitamin-C-Gehalt von Blut und Liquor nach intravenösen Redoxgaben. [The vitamin C content of blood and cerebrospinal fluid after intravenous administration of Redoxon.] *Schweiz. med. Wochenschr.*, 1955, 85, 127-128. [Med. Poliklin., Univ. Basle.]

Ascorbic acid was estimated by the method of Roc and Knether (Abst. 261, Vol. 13) in the blood and cerebrospinal fluid of 21 patients with polymyelitis, 1, 3, 6 and 24 hr. after intravenous injection of from 3.5 to 14.0 g. ascorbic acid. The values in the serum, in mg. per cent., were, after 1 hr. between 10 and 24, after 3 hr. between 6 and 17, and after 6 hr. between 3.6 and 5.1. No value for the cerebrospinal fluid after 1 and 6 hr. was above 6 mg. per cent. Both sets of values fell slowly to about 4 after 24 hr.—E. M. Hume.

Of 32 patients with 17 different diseases including rheumatoid arthritis, the majority, but not all, responded to treatment with cortisone acetate or adrenocorticotrophic hormone by an increase in the amount of ascorbic acid in the urine, whether the intake of ascorbic acid was small or large.

E. M. Hume.

5653

CHAKRABARTI, B. and BANERJEE, S. Dehydroascorbic acid level in blood of patients suffering from various infectious diseases. *Proc. Soc. Exp. Biol. Med.*, 1955, 88, 581-583. [Dept. Physiol., Presidency Coll., Calcutta.]

The concentration of dehydroascorbic acid in the blood of patients with meningococcal and tubercular meningitis, tetanus, acute lobar pneumonia and typhoid fever was greater than normal; values were highest in those who ultimately died. Ascorbic acid values were correspondingly low. During convalescence dehydroascorbic acid decreased and ascorbic acid increased. It is suggested that for prognostic purposes dehydroascorbic acids should be estimated in all patients with acute infection.—A. Hepburn.

HOROSCHAK, S. 4. Clinical applications of the synergists; ascorbic acid and hesperidin.

MARTIN, G. J. 5. Conclusions. *Exp. Med. Surg.*, 1954, **12**, 535-544; 545-563; 563-569; 570-597; 597-598. [National Drug Co. Philadelphia, Pa.]

1. An account is given of the structure of flavones, chalcones and flavonoids which have been isolated or synthesised and shown to have biological importance.

2. The present knowledge of capillary permeability and capillary flow is reviewed, and theories of the transcapillary transfer of crystalloids and colloids, and problems of haemostasis and oedema are discussed.

3. Possible mechanisms for the action of vitamin P substances and their interaction with ascorbic acid are discussed with reference to their effect on the permeability and fragility of the vascular system as well as on tissues in general.

4. The wide range of the clinical applications of ascorbic acid and hesperidin is briefly reviewed in relation to vascular purpura, habitual abortion, eczema, rheumatic fever, psoriasis, diabetic retinopathy, haematuria, haemorrhagic nephritis and hypertension. Numerous single reports of treatment in other diseases are mentioned.

5. The editor of the series of reviews summarises the material with emphasis on the enormous extent of the capillary system and the significance of the intercellular substance. He considers that there is no disease in which benefit may not be expected by assuring capillary strength and integrity, and that ascorbic acid and flavonoids are fundamentally concerned in preserving them.

MIYAKE, T. and KOJIMA, Y. **Eye diseases and capillary fragility. 1. Incidence of increased capillary fragility in eye diseases: rutin therapy.** *Nagoya Med. J.*, 1954, **2**, 125-137. [Dept. Ophthalmol., Nagoya City Univ. Med. Sch.]

Capillary resistance was measured by 2 positive-pressure methods; in one the pressure applied was fixed at 35 mm. Hg. and in the other it was that previously ascertained as midway between the subject's systolic and diastolic pressure. They are referred to as the fixed-pressure and blood-pressure methods. Of 220 persons, normal and

otherwise, 150 were tested by both methods, 28 by the fixed-pressure method only, and 42 by the blood-pressure method only. The number of normal subjects tested was between 50 and 60; the percentage with increased capillary fragility was 5.5 by the fixed-pressure method and 20.7 by the blood-pressure method. In all the subjects, normal and abnormal together, the corresponding percentages were 11.2 and 48.5. The results in the various disease groups fell roughly into the same order by the two methods, but the blood-pressure method appeared more sensitive and gave a wider range of results. Increased capillary fragility was most frequent in vascular hypertension and glaucoma; in retinal haemorrhage of undifferentiated origin and in diabetes it was less.

A preliminary report is made on treatment with rutin in a minimum daily dose of 100 mg. given orally. Capillary resistance usually returned to normal but did not always remain so unless the dose was increased, and deteriorated rapidly if treatment was withdrawn. In a few patients with retinal haemorrhage no unequivocal evidence of benefit from therapy with rutin could be obtained.

Zürich.] English summary.

Konakion (Hoffmann-La Roche, Basle) is a preparation of vitamin K₁ so finely dispersed with an emulsifier that it can be injected intravenously. A very rapid result is thereby obtained where it is desired to reverse the excessive effect of dicoumarol. It was tested on 40 patients having dicoumarol preparations, and within 2 hr. after injection of from 5 to 10 mg. Konakion, there was an increase in the concentration of prothrombin and factor VII.—E. M. Hume.

KING, J. D., MELLANBY, M., STONES, H. H. and GREEN, H. N. The effect of sugar supplements on dental caries in children. *Med. Res. Council. Spec. Rep. Ser. No. 288*, 1955, pp. viii + 55. H.M.S.O., London. Price 4s. net.

Investigations were made at 3 separate centres. In London there were 3 groups of young children who were between 2 and 4 years of age when the work began. They resided in a number of institutions and the numbers under observation in the control, white-sugar and brown-sugar groups were, respectively, for 1 year 126, 151 and 114; for 1½ years 69, 90 and 65; for 2 years 30, 32 and 20. The pattern of their diets was examined and the estimated total sugar contents in the same order were 11, 22½, 21½ oz. weekly per child, these average amounts being roughly comparable with the low war-time and the higher pre-war consumption in Britain. Data are tabulated to show the number of caries-free children, the incidence,

extent and spread of caries among the children and the numbers of teeth affected. There was no evidence that the higher intake of sugar affected either the initiation or the spread of caries in deciduous teeth.

In Liverpool the children were between 4 and 14 years of age and were inmates of one institution. The numbers under observation for 1, 1½ and 2 years in control and sugar groups, respectively, were 112, 113; 91, 90; 83, 78. The estimated total weekly intakes of sugar were 15 and 37 oz. per child, the added sugar being refined white. Data are presented for deciduous molars in children of 4 to 10 years and for permanent first molars in those of 4 to 14 years to show incidence, extent and spread of caries. The findings for the age groups were conflicting, but there was again no positive evidence that sugar was decisive in favouring caries development.

In Sheffield the children were also between 4 and 14 years of age and were living in cottage homes. The numbers studied in control and sugar groups, respectively, were for 1 year 57, 89 and for 1½ years, 36, 57. Their average weekly consumption in winter was 19½ and 41½ oz. per child, the extra being white refined sugar. In summer these amounts were increased by 4 oz. for some weeks when sugar was made available for jam-making. Data are given which are comparable with those for Liverpool. Numbers were small and results, like those for Liverpool, sometimes conflicting, but again no adverse effect of extra sugar was demonstrated.

It is concluded that, if the diets of children attain the standards of those provided in these institutions, then relatively great increases in the intake of sugar, either white or unrefined, may occur without resulting increases in the incidence or rate of spread of caries.

Subsidiary investigations were made in Liverpool. Additional sugar had no effect on lactobacillus counts or on acid production in saliva. Buffering capacity of saliva increased with age to an extent greater in the control than in the sugar group, but the difference between the groups in rates of increase was not significant.—D. Harvey.

5665

LENNON, D. F. and SULLIVAN, H. R. The relative rates of acid production from "refined" and "natural sugars". *Dent. J. Austral.*, 1955, 27, 67-71. [Dept. Prev. Dent., United Dent. Hosp., Sydney.]

Acid production by lactobacillus cultures under standard conditions with the forms of sugar and its products which are in common use was measured *in vitro* by titration at intervals of 24 hr. Fermentation was more rapid with the group consisting mainly of monosaccharides, golden syrup,

honey and treacle, but total production of acid was greatest with a dissaccharide, white sugar. In experiments with shorter intervals the process was continuous during the first 5 hr. of incubation with those of the first group; in that time no acid was produced with sugars of the second type. Changes during incubation in the pH of sugar solutions and of mixtures of these with a concentrate prepared by centrifuging saliva were also studied. The fall in pH began at once with monosaccharides but was delayed for nearly 30 min. with the disaccharides; with the concentrate the rate of change in pH was similar with both forms.

The conclusions were that the selective action of lactobacilli may limit their importance as producers of acid in the mouth and that there was no evidence that so-called natural sugars like honey were of less consequence than refined sugar in initiating caries.—D. Harvey.

DIRKS, O. B. Fluorootoediening als cariesprophylacticum. [Administration of fluorine as a preventive of caries.] *Voeding*, 1955, **16**, 315-326. [Hyg. Lab., Rijksuniv., Utrecht.] English and French summaries.

An experiment on the fluoridation of drinking water was begun in 1953 in Holland at Tiel, with the population of Culemborg as a control group receiving no additional F. The extra F is supplied as 1.1 mg. NaF per litre water and the incidence of caries will be studied in alternate years in the child population between 11 and 15 years of age. M. Eddison.

5668

NATIONAL RESEARCH COUNCIL, U.S.A., FOOD AND NUTRITION BOARD. **The problem of providing optimum fluoride intake for prevention of dental caries.** Publ. No. 294, November 1953, pp. 15. Price \$0.50.

The optimum level of F intake is defined as "that which in epidemiological and clinical observations has been found to combine the highest degree of caries protection with the lowest degree of mottled enamel". The magnitude of the caries problem is indicated and the efficacy and safety of fluoridation of water are taken as proved. The advantages of supplying F in water are balanced against the disadvantages of other vehicles such as milk, flour, babies' canned foods or bottled fluoridated water. Vehicles other than water would require further study in adequately controlled experiments before they could be accepted as better.—D. Harvey.

5669

HILL, I. N. **Evanston dental caries study. 12. A survey of lactobacillus counts with reference to untreated carious surfaces before and after exposure to fluoridated water.** *J. Dent. Res.*, 1955, **34**, 178-187. [Zoller Mem. Dent. Clin., Univ. Chicago, Ill.]

For a preliminary report see Abst. 999, Vol. 20. The present paper is based on specimens of saliva collected during the period 1946 to 1953 from over 2200 children aged from 6 to 8 and from 12 to 14 years. When these were grouped according to lactobacillus count (low, including negative; moderate; high), there was found not only the usual association between lactobacillus count and incidence of caries, but also a reduction of caries within the low and moderate lactobacillus count groups in the years subsequent to the addition of fluorine to the drinking water (begun in 1947). Shifts of distribution of lactobacillus counts indicated a reduction of lactobacillus activity in the younger children; the evidence for the older children was less clear.—W. M. Deans.

perience with intravenous infusion of emulsified fat. *J. Lab. Clin. Med.*, 1955, **45**, 697–710. [Dept. Nutrit., Harvard Sch. Pub. Health, Boston, Mass.]

Data are presented on the incidence of pyrogen and colloid effects, chills, vasomotor changes and other reactions during the infusion of emulsified fat.

In all 1466 infusions were given to 426 patients. Emulsions containing 10 to 15 per cent. coconut, olive, groundnut or cottonseed oil or synthetic triolein were used. The percentages of infusions causing no pyrogen reaction were for cottonseed oil 91, coconut 86, olive 82, groundnut 83 and triolein 76.—F. C. Aitken.

[Effect of tests doses of glucose, fructose and galactose on metabolism of juvenile diabetics.]** *Ann. paediat., 1955*, **184**, 287–293. [I. Kinderklin., Med. Univ., Budapest.] English and French summaries.

Single and double blood sugar tolerance tests were made in 14 diabetic children given test doses of glucose, fructose or galactose. Glucose produced the greatest rise in blood sugar, more than 100 mg. per cent. in half the tests, and galactose the least, with the rise exceeding 50 mg. in only 4 tests. After glucose there was a fall in blood ketones only when the blood sugar was extremely high, and usually there was some increase in ketones. The ketogenic effect of fructose was less than that of glucose in 9 out of 10 tests, but galactose and glucose were similar in effect.

It is suggested that those diabetic children who have low blood sugar at night and ketosis in the morning should be given fructose at night.

DÜR, A. Beitrag zur Diättherapie akuter Ernährungsstörungen beim Säugling. [Dietary treatment of acute nutritional upsets in infants.] *Öst. Ztschr. Kinderheilk.*, 1955, 11, 112-116. [Gottfried von Preyersches Kinderspital, Vienna.]

The combined use of two proprietary foods in infantile dyspepsia is described. Aröbon, a preparation of carob bean meal, and Pelargon, a milk and orange juice concentrate, were given in increasing amounts to infants with severe diarrhoea. The results were highly satisfactory; an infant aged 2 months which was losing weight improved in appetite and began to gain weight on the new treatment. The dietary therapy was successful in more than 20 patients with dyspepsia.

WILLS, V. G. and JELLIFFE, D. B. The management of gastro-enteritis in Jamaican infants. *West Indian Med. J.*, 1954, 3, 213-230.

During the last 2 years over 150 infants have been treated for gastro-enteritis in the University College Hospital, Jamaica. Most of them were malnourished and some had kwashiorkor or nutritional marasmus; parenteral infection was rare.

Two schemes of treatment are described in detail, for hospitals with or without laboratory facilities. They follow the usual lines, with antibiotics to combat infection, and oral and parenteral fluids to correct water and electrolyte imbalance, and subsequently with graduated milk feeds over a period of 7 to 10 days. Vitamins are not given till then, unless signs of deficiency, especially of riboflavin, have already appeared; if so, 10 mg. riboflavin daily may be given by injection. For persistent vomiting, 5 mg. vitamin B₁ daily by injection may be tried. Since nearly all the infants with gastro-enteritis are anaemic, Fe is given in liquid form, either sulphate or ammonium citrate, during convalescence. Suggestions for the treatment of persistent mild diarrhoea without fever but with failure to gain weight despite apparently adequate food intake include the local foods ripe bananas, from 3 to 6 daily according to age of infant, beaten into a pulp with skimmed milk, and carob bean, 5 teaspoonfuls of the powdered beans mixed with 5 oz. skimmed milk and filtered. Another local suggestion is coconut water, by mouth only, as a source of potassium; according to a small series of estimations on Jamaican coconuts, it contains on the average 68.4 m. equiv. K per litre.—W. M. Deans.

5691

SCHLESINGER, B., PAYNE, W. and BLACK, J. Potassium metabolism in gastroenteritis. *Quart. J. Med.*, 1955, 24, 33-48. [Hosp. Sick Child., Gt. Ormond St., London.]

Of 653 infants with gastro-enteritis 67 had low levels of K in serum at some stage of their illness. In 37 infants the condition was associated with abdominal distension. Distension occurred in 8 others. High levels of K in serum were found at some stage of the disease, usually during the dehydration phase, in 29 infants, but many of them subsequently had low levels.

In gastro-enteritis, treatment with K should be delayed until dehydration has been corrected.

ROSS, C. A. C., FRAZER, A. C., FRENCH, J. M., GERRARD, J. W., SAMMONS, H. G. and SMELLIE, J. M. Coeliac disease. The relative importance of wheat gluten. *Lancet*, 1955, 268, 1087-1091. [Dept. Pharmacol., Univ. Birmingham.]

Treatment with a diet free from wheat gluten was successful in 28 of 30 children with chronic steatorrhoea and normal pancreatic function. When wheat gluten was restored to the diet of 12 of the 28 steatorrhoea recurred. Of the 2 remaining children one appeared to have a deficiency of bile salts and the other showed fat intolerance dating from an attack of gastro-enteritis in infancy.

The term gluten-induced coeliac disease is suggested for the disorder in those children who recover on diets free from wheat gluten.

F. C. Aitken.

5695

GERRARD, J. W., ROSS, C. A. C., ASTLEY, R., FRENCH, J. M. and SMELLIE, J. M. Coeliac disease: is there a natural recovery? *Quart. J. Med.*, 1955, 24, 23-32. [Dept. Paediat., Univ. Birmingham.]

Thirty-two patients aged from 4 to 19 years in whom coeliac disease had been diagnosed were re-examined. None had been treated with a diet free from wheat gluten. Clinical, biochemical and radiological findings showed that none had completely recovered.—F. C. Aitken.

RAE, J. W. and ALLISON, R. S. The effect of diet and regular living conditions on the natural history of peptic ulcer. *Quart. J. Med.*, 1953, 22, 439-455.

Sixty-three men were under observation for over 12 months in an experimental scheme for the rehabilitation and employment of men of the Royal Navy suffering from peptic ulcer. Diet was strictly controlled and there was constant medical care. Observations made during the experiment and data obtained in replies to a questionnaire issued 5 years later suggest that in this series of patients the natural history of the disease was not materially influenced by the prolonged medical treatment.—F. C. Aitken.

5698

OGLE, J. C. and HARVEY, C. M. (Jr.) Hypercalcemia and renal impairment following milk and alkali therapy for peptic ulcer. *Southern Med. J.*, 1955, 48, 126-129. [Veterans Admin. Hosp., McKinney, Tex.]

A case is described. On admission to hospital the diet was of milk and cream, CaCO_3 1.0 g. every hour and MgO 2.5 g. once daily. After 3 weeks the patient was drowsy and inclined to vomit. Serum Ca values of 15.6 and 16.0 mg. per 100 ml. were found, with raised values for blood urea and creatinine. Band keratopathy was present in the left cornea. Before admission to hospital the patient had taken about 250 g. baking soda every 3 days and from 4 to 8 oz. cheese daily. When given a diet with less than 200 mg. Ca daily and with a supplement of NaCl and KCl the patient quickly improved. The clinical features agreed with those in 12 other cases reported in the literature.—E. M. Hume.

5699

BLAKE, J. and RECHNITZER, P. A. The haematological and nutritional effects of gastric operations. *Quart. J. Med.*, 1953, 22, 419-437. [Dept. Med., Univ. Edinburgh.]

Three groups of patients were studied: 104 cases of partial gastrectomy, 65 of gastro-enterostomy and 10 of total gastrectomy. In the first group Fe-deficiency anaemia occurred in 40 per cent. of male and in 45 per cent. of female patients. There was no evidence of anaemia in the second group. In the last group there were 6 cases of macrocytic anaemia and 2 of Fe-deficiency anaemia. Signs of vitamin B deficiency occurred in 4 per cent. of the men and 5.5 per cent. of the women in the first group, in 3 of the 10 patients in the last group and in none of the second group. Assessment of

sub-nutrition on the bases of weight loss and diminished working capacity depended on the patients' statements on their capacity for work and on their evidence of previous weight. Only in the last group was the incidence of sub-nutrition high.—F. C. Aitken.

5700

Discussion on toxic and nutritional disturbances in the small intestine associated with surgery of the gastro-intestinal tract. *Proc. Roy. Soc. Med.*, 1955, 48, 245-252.

Disorders of the small intestine after gastro-intestinal surgery are classified and discussed. Vitamin B₁₂ deficiency and anaemia are dealt with by L. J. Wills.—F. C. Aitken.

5701

HAYES, M. A. The dietary control of the post-gastrectomy "dumping syndrome". *Surgery*, 1955, 37, 785-793. [Samuel C. Harvey Metabol. Unit, Dept. Surg., Sch. Med., Yale Univ., New Haven, Conn.]

Seven patients showing the dumping syndrome and failure to gain weight responded satisfactorily to treatment with diets high in fat and protein and low in carbohydrate. Weight curves for 6 of the patients and detailed energy and N balance data for the seventh are presented. A satisfactory diet for such patients is one in which energy from carbohydrate, protein and fat is in the ratio 1:1.5:5.—F. C. Aitken.

5702

MONTGOMERY, T. L. and PINCUS, I. J. A nutritional problem in pregnancy resulting from extensive resection of the small bowel. *Amer. J. Obstet. Gynecol.*, 1955, 69, 865-868. [Dept. Obstet. Gynaecol., Jefferson Med. Coll., Philadelphia, Pa.]

In a patient with nutritional problems after extensive resection of the small intestine a remarkable improvement in digestive tract function occurred during pregnancy.—F. C. Aitken.

5703

ANDRÉ, L. M., LAMY, L. and AGBOTON, D. Alimentation supplémentaire par le lait écrémé. Ankylostomose et gains pondéraux chez l'enfant africain. [Supplementary feeding with skimmed milk. Ankylostomiasis and weight increase in the African child.] *Bull. Soc. Pathol. exot.*, 1954, 47, 535-539. [Hôp. Gén., Brazzaville.]

During their stay in hospital 92 children were given daily supplements of milk, 40 g. to children under 5 years of age and 80 g. to the older children. Carbon tetrachloride and an extract of chenopodium were given for the ankylostomiasis and the results

of treatment were based on the laboratory examination of the stools. Removal of parasites led to some gain in weight but gains were commoner and greater when a milk supplement was given as well. L. Wills.

KRISS, J. P., CARNES, W. H. and GROSS, R. T. Hypothyroidism and thyroid hyperplasia in patients treated with cobalt. *J. Amer. Med. Assoc.*, 1955, 157, 117-121. [Dept. Med., Stanford Univ. Sch. Med., San Francisco, Calif.]

Five patients were given coated pills of CoCl₂ with amounts varying from 2.8 to 3.9 mg. per kg. bodyweight daily for from 3 to 7½ months. Hyperplasia and hypofunction of the thyroid gland developed. In 3 of the patients goitre developed gradually, enlargement of the thyroid increasing during Co therapy and disappearing within several weeks after Co was withheld. There was evidence of decreased uptake of radio-active I and 1 case of serious clinical myxoedema. It is suggested that Co must be regarded as a goitrogenic agent which ought not to be used indiscriminately, especially for infants and children. Several hypotheses of the mechanism of the antithyroid effect of cobalt are advanced and discussed.

B. W. Simpson.

5706

NORMAN, N. The incidence of hyperthyroidism, hypothyroidism and diabetes in Northern and Southern Norway, a comparative study. *Acta med. scand.*, 1955, 151, 185-190. [Troms and Tromsøe Hosp.]

Complete records of all patients with hyperthyroidism, hypothyroidism and diabetes at Troms and Vestfold Hospitals in Norway from 1942 to 1951 are the basis of this study. Troms County is north of the Arctic circle and Vestfold is in the most southern part of Norway. The amount of sunshine available in Troms is only a fraction of that in Vestfold. In Troms there are Finns and Lapps as well as Norwegians; in Vestfold the population is mostly Norwegian.

There were 839 patients in all, 628 from Vestfold and 211 from Troms. The distribution of the different diseases, their annual incidence and other data are tabulated. The incidence of hyperthyroidism in Vestfold was many times that in Troms; that of hypothyroidism was greater. in

N.A. and R., October 1955

Troms than in Vestfold. Diabetes was more frequent in Troms than in Vestfold.

B. W. Simpson.

ANAEMIA

5707

ARMAS CRUZ, R. Clasificación y fisiopatología de las anemias. [Classification and physiopathology of anaemias.] *Rev. méd. Chile*, 1955, **83**, 73-82. [Cát. Med., Univ. Chile.]

5708

COLLES, B. L. The use of cobalt in some common anaemias of childhood. *Arch. Dis. Childhood*, 1955, **30**, 121-126. [Dept. Paediat., Elizabeth Garrett Anderson Hosp. (Royal Free Hosp. Group), London.]

Fifty children with anaemia refractory to treatment with Fe were given Co. All but one, a case of *erythrogenesis imperfecta*, responded in Hb and red cell count. Most of the cases were of anaemia secondary to infection or anaemia of prematurity. Further examination of 12 in whom marrow was studied before and after treatment showed erythroid hyperplasia in 9. The mode of action of Co is discussed.—F. C. Aitken.

5709

STEWART, (I. T. Environmental factors in anaemia and infection in Pakistan. *Proc. Roy. Soc. Med.*, 1955, **48**, 291-295 [with discussion 295]. [Dow Med. Coll., Karachi.]

Hb levels were estimated in a representative sample of over 1000 Karachi women and the results were classified according to the subject's social status. Anaemia was prevalent and increased in incidence from the group of highest to that of fourth highest social status and then decreased in the fifth group of lowest social status. Anaemia was most prevalent in the age group 15 to 30 years. Most of it was of simple nutritional type.

A study of intestinal parasitic infection in a group of over 1000 men and women showed it to be widespread, but incidence was not related to income, community or type of home.

5710

CHAUDHURI, S. Hydrolysed protein and milk powder in the treatment of anaemia in India. *J. Trop. Med. Hyg.*, 1955, **58**, 56-63. [Haematol. Res. Lab., Safadr Jang Annexe Hosp., New Delhi.]

Sixty patients with macrocytic, normocytic or microcytic, normochromic or hypochromic anaemia were treated in groups with milk powder, milk or meat protein hydrolysates, hydrolysates of mixed animal and vegetable protein or a groundnut

protein preparation. Treatment with the animal protein preparations caused significant improvement in values for plasma protein, Hb, red cell count and packed cell volume and in clinical condition.—F. C. Aitken.

5711

WOODBUFF, A. W. The natural history of anaemia associated with protein malnutrition. *Brit. Med. J.*, 1955, **i**, 1297-1307. [London Sch. Hyg. Trop. Med., Univ. London.]

In these Goulstonian Lectures data from Nigeria, additional to those dealt with in Abst. 5418, Vol. 21, are presented. In studies of 45 pregnant women in whom, late in their pregnancy, anaemia was often severe, treatment with Fe, folic acid, liver extract or vitamin B₁₂ was ineffective. Of the possible causes considered, presence of intestinal or malarial parasites or deficiency of dietary protein, the last was concluded to be the operative one and to give rise to histological changes in liver and chemical and electrophoretic changes in blood proteins. From cytological examination of liver tissue the cells were found to be thinner than normal. These findings in pregnant women, in a high proportion of whom pregnancies were twin, prompted similar studies in other subjects on whose supplies of protein demands were also likely to be heavy. Similar results were obtained in groups of 9 children with kwashiorkor and of 21 older children and young adults who were anaemic.

Treatment was by providing a well balanced diet with a daily supplement of casein, about 2 oz. for the children and from 2 to 4 oz. for the pregnant women. Results were poorest for the third group of patients, in whom the disease appeared to have reached an irreversible stage. The occurrence of nutritional macrocytic anaemia associated with liver damage as it may affect the subject at different stages of his life history is summarised in schematic form.—D. Harvey.

5712

GATENBY, P. B. B. and LILLIE, E. W. Iron-deficiency anaemia in pregnancy. *Lancet*, 1955, **268**, 740-743. [Rotunda Hosp., Dublin.]

Blood samples taken from 4314 patients on first attendance at the antenatal clinic showed Hb values below 10 g. per 100 ml. in 1027. The incidence of anaemia rose in winter. A special study of 397 of the women with anaemia showed that 34 per cent. were without symptoms of the disease. Only in those with Hb values below 6 g. were symptoms constantly present. From case history data it was concluded that deficiency of Fe in the diet was the most important cause of this anaemia; very few patients did not respond to Fe therapy in some form.—F. C. Aitken.

5713

Discussion on anaemia in general practice. *Proc. Roy. Soc. Med.*, 1955, **48**, 347-354.

The diagnosis and treatment of iron-deficiency and hypochromic anaemias of pregnancy are described by Dr. D. G. French and the management in practice of other forms by Dr. M. C. G. Israels.—F. C. Aitken.

5714

JANDL, J. H. **The anemia of liver disease: observations on its mechanism.** *J. Clin. Invest.*, 1955, **34**, 390-404. [Thorndike Mem. Lab., Second and Fourth Med. Serv. (Harvard), Boston City Hosp., Mass.]

This detailed study of the blood and bone marrow of 20 alcoholics with cirrhosis and anaemia included some nutritional tests which will be published separately. In 4 of the patients folic acid deficiency complicated liver cirrhosis and morphologically these were in a group apart from the remaining 16. The mechanism of the anaemia of uncomplicated liver disease is discussed at length.—F. C. Aitken.

5715

O'BRIEN, J. R. P., TAYLOR, W. H., TURNBULL, A. L. and WITTS, L. J. **An apparently homogeneous substance with intrinsic-factor activity associated with cell particles from human stomach.** *Lancet*, 1955, **268**, 847-848. [Dept. Biochem., Radcliffe Infirmary, Univ. Oxford.]

The preparation of the active substance E is described. In tests on patients with pernicious anaemia substance E promoted absorption of 32 per cent. of radio-active vitamin B₁₂ in a dose of 10 mg.—F. C. Aitken.

OTHER CONDITIONS

5716

HAGEDORN, H. C. **Anorexia nervosa.** *Acta med. scand.*, 1955, **151**, 201-208. [Niels Steensen's Hosp., Gentofte, Denmark.]

Of 17 suspected cases of *anorexia nervosa* referred to the hospital for treatment the diagnosis was confirmed in only 8.—F. C. Aitken.

5717

MARQUEZY, R. A. and DEBRAY, P. **La rehidratación en la toxicosis del lactante. [Rehydration in infantile toxicosis.]** *Rev. española Pediatr.*, 1955, **11**, 99-107. [Paris.] French, English and German summaries.

Extracellular dehydration characterised by hypotonic plasma and cell hyperhydration results from excessive loss of electrolytes and is relatively rare; it is controlled by injection of hypertonic

saline. More common is primary extracellular dehydration with hypertonic plasma and secondary cell dehydration; it occurs when loss of water is greater than that of electrolytes, as seen in neurotoxicosis.

In this condition it is important to recognise the urgent need for rehydration when the loss of weight is 10 or 15 per cent., whether or not other clinical signs are present. The mental state is also an important guide to the need for rehydration. Depression of the freezing point of plasma or cerebrospinal fluid is of confirmatory value.

Isotonic glucose serum [not defined] is the treatment preferred. When the loss of weight is less than 10 per cent., glucose in saline or water may be given by mouth; this is possible when the infant can swallow easily. In more advanced dehydration the subcutaneous route is used, but when the infant is comatose immediate intravenous perfusion is called for. Satisfactory responses to rapid intravenous perfusion with plasma or glucose solution are obtained even in vascular collapse. Combination of rehydration with antibiotics is advisable in neurotoxicosis.—D. Duncan.

Little is known of the causes and mechanism of obesity in man and a review of experimental animal studies suggests that the problem is more complex than is often supposed. (See also Review Article, pp. 596 and 871, Vol. 25.)

F. C. Aitken.

5720

WERNER, S. C. (with BARBER, S., MOEN, I., ILES, M. and KERR, A.). **Comparison between weight reduction on a high-calorie, high-fat diet and on an isocaloric regimen high in carbohydrate.** *New Engl. J. Med.*, 1955, **252**, 661-665. [Dept. Med., Coll. Phys. Surg., Columbia Univ., New York.]

A high-fat diet was not superior to a high-carbohydrate diet in inducing weight loss in 6 obese subjects when the intake from either diet was about 2870 Cal. daily.—F. C. Aitken.

5721

La resistenza dell'obeso alla diminuzione di peso. [The resistance of the obese to loss of weight.] *Acta gerontol.*, 1954, **4**, 192-194.

N.A. and R., October 1955

A discussion of literature about the psychogenic causes of obesity.—D. Duncan.

5722

ØSTRGAARD, L. On psychogenic obesity in childhood. 5. *Acta paediat.*, 1954, 43, 507-521. [Gersonsvej, Hellerup, Denmark.] German, Spanish and French summaries.

For previous parts see Absts. 5116, Vol. 23; 2437, Vol. 24. This part relates to 20 boys and 38 girls between 4 and 14 years treated for obesity in Queen Louise's Children's Hospital, Copenhagen during 11 months in 1949 and is based on interviews and mental tests; less precise information for comparison was also collected about 46 normal children matched for age.

The appetite of 44 of the obese children was considered by their parents to be large and there was evidence that most of the other children were large eaters also; unless prevented, 49 habitually ate between meals. Some were gourmets, others gluttons. Favourite foods were potatoes and thick gravy, bread and butter and jam, pancakes, puddings and mashed potatoes. Forty-five were inactive, but there was no direct relation between activity and degree of obesity.

Intelligence quotients were normally distributed, but 49 showed signs of emotional difficulty, e.g., failure to adapt to other children. Abnormal family relationships were found, in 14 the typical Bruch set-up (see Abst. 5116, Vol. 23 for references) but in others direct rejection or over-exaction by parents, or difficulties arising from death or separation of parents or the arrival of a new baby. For some children eating seemed to be a consolation, for others an outlet for aggressiveness. Rorschach testing indicated that they were unusually impulsive and receptive.

W. M. Deans.

5723

GUTMAN, A. B. and Yü, T. F. Prevention and treatment of chronic gouty arthritis. *J. Amer. Med. Assoc.*, 1955, 157, 1096-1102. [Dept. Med., Mount Sinai Hosp., New York.]

Treatment of gout has hitherto consisted more in measures to control acute attacks rather than to check gradual accumulation of uric acid in the tissues. For the latter purpose, a combination of diet regulation and treatment with Probenecid and small amounts of colchicine daily is described, which reduced serum uric acid values to below 7 mg. per 100 ml. in all but 3 of 30 patients. Joint stiffness or pain disappeared or was reduced in most, and tophi became smaller, though associated bone lesions persisted. Five case histories are given, with photographs of hands or feet.

For diet regulation, uric acid in serum and 24-hr. excretion in urine are estimated before and after 10 to 14 days on a basal diet low in purines and

fat and containing 60 to 70 g. protein exclusively from cereals, grain products, eggs, cheese, milk, non-leguminous vegetables and fruit and supplying about 2000 Cal. In 96 of 114 patients serum uric acid fell, in 22 by from 2 to 4 mg. per 100 ml., but on the average by only 1.1 mg. Though the effect of diet is modest, it is considered valuable. The studies are repeated after adding 4 oz. (60 g.) [as in text] meat, fish or fowl; from the results, together with the effect of Probenecid, the permissible quota of flesh protein is arrived at, generally 2 to 4 oz. (60 to 120 g.) several days a week, daily in some.—W. M. Deans.

5724

SCHOLZ, D. A. and KEATING, F. R. (Jr.) Milk-alkali syndrome. Review of eight cases. *Arch. Int. Med.*, 1955, 95, 460-468. [Sect. Med., Mayo Clin., Rochester, Minn.]

Case histories are given of patients who had raised blood Ca, renal insufficiency with retention of N and, sometimes, alkalosis. As treatment for gastric ulcers they had taken, with their milk diet, large quantities of absorbable alkali; when this was replaced by aluminium hydroxide gel, recovery was rapid and uneventful.—D. Harvey.

5734

NISENSEN, A. Hypoproteinemia and edema in eczema. *J. Pediat.*, 1955, **46**, 554-551. [Los Angeles Child. Hosp., Calif.]

A table is presented showing levels of total protein, albumin, globulin and N.P.N. in the blood, the incidence of infections, the degree of oedema and weeping of the skin and the sources of protein in the diets of 24 infants with eczema. There was

clinical oedema in 8; levels of albumin were low in 18 and of globulin low in 5. It appeared that the conditions predisposing to oedema were extensive weeping of the skin, a diet poor in animal protein, and infection. The oedema responded to treatment with meat or amino-acids by mouth or with blood or amino-acids by vein.—F. C. Aitken.

5735

ARMSTRONG, M. D. and TYLER, F. H. Studies on phenylketonuria. 1. Restricted phenylalanine intake in phenylketonuria. *J. Clin. Invest.*, 1955, **34**, 565-580. [Lab. Study Hereditary and Metabol. Disorders, Coll. Med., Univ. Utah, Salt Lake City.]

In 5 children correction of the biochemical abnormalities by restriction of phenylalanine intake was accompanied by some clinical improvement, notably control of convulsions, but no consistent effect on mental condition was seen.—F. C. Aitken.

5736

MARCOS LANZAROT, M. Estudios sobre la jaqueca. Revisión de observaciones realizadas durante veintisiete años. [Studies on migraine. Review of observations covering twenty-seven years.] *Rev. clín. española*, 1955, **56**, 302-312. English, German and French summaries.

In a general discussion on migraine the following data are given, for a patient considered to be typical. The oculo-cardiac reflex was normal on days when there was no migraine attack, but was reversed during an attack. The white blood cell count fluctuated irregularly. During an attack blood Ca rose from a normal value of 10 mg. per 100 ml. to 16. The B.M.R. [standard not stated] varied considerably, from +3 per cent. on a normal day to -12 per cent. on a day of moderate migraine. There was oliguria before an attack and polyuria later. Acetonuria was common. Blood sugar was normal, but when the patient was given a ketogenic diet there was an intense attack of migraine with low blood sugar. Sugar tolerance tests on a normal day produced a final drop in blood sugar. The alkali reserve was very high during an attack. Vomitus contained no free HCl, and the sediment contained eosinophils, suggesting angioneurotic oedema of the gastric mucosa. The electrocardiogram is described.

The etiology of migraine is discussed with reference to these findings and to the literature.

GŁOGOWSKI, G. Die Bedeutung von Ernährungsschäden für den Verlauf extrapulmonaler Tuberkulosen und die Wirksamkeit der anti-biotisch-chemotherapeutischen Behandlung. [The significance of nutritional disorders for the course of non-pulmonary tuberculosis and

N.A. and R., October 1955

for the efficacy of chemotherapy and treatment with antibiotics.] *Münch. med. Wochenschr.*, 1955, 97, 11-13. [Staatl. Versorgungskrankenhäus, Bad Tölz.]

In patients with tubercular lesions of the intestine or bones the general nutritional condition was often poor and treatment was ineffective until better nutrition was instituted. Vitamins were found to be of primary importance and a multi-vitamin preparation is recommended. It was necessary to give large doses of vitamins for several months to some patients before healing began in response to chemotherapeutic or antibiotic treatment.—A. M. Copping.

LENNERTS, L. Der Einfluss verschieden hoher Rauhfuttermengen und Eiweisszulagen auf die Verdaulichkeit des Futters, nach Versuchen an Schafen. [Effect of different amounts of roughage and protein supplements on digestibility of the fodder in experiments with sheep.] *Arch. Tierernährung*, 1954, 4, 79-132. [Inst. Tierernährungslehre, Humboldt Univ., Berlin.]

The first series of experiments was on 2 Merino mutton type wethers 2 to 3 years old and weighing 62 to 72 kg. They were fed on chaffed hay twice daily and water was always available. Each study consisted of a pre-period of 8 days and a balance trial lasting 10 days. The quantities of hay were varied and 3 different hays were used. Digestibility results are fully tabulated and statistically analysed.

Intakes of between 600 and 1400 g. of hay did not significantly affect the percentage digestibility of crude protein, fibre or fat; digestibility of N-free extract did not differ at intakes of 800 and 1200 g. hay, but between 600 and 1400 g. there was a decrease.

With the same 2 sheep the effect of a protein supplement of soya bean meal was studied; the intakes were 600 or 1000 g. hay and 250, 400 or 550 g. soya bean meal, and in one experiment 1400 g. hay and 550 g. meal. With increasing protein intake digestibility of hay protein fell, especially when the hay intake was low. With 1000 g. hay the protein supplement increased the digestibility of the crude fat of the hay. There was no effect on digestibility of fibre or N-free extract.

It is concluded that a medium amount of roughage is necessary for the best utilisation of feed by sheep.—D. Duncan.

5745

RAYMOND, W. F., HARRIS, C. E. and KEMP, C. D. **Studies in the digestibility of herbage. 6. The effect of level of herbage intake on the digestibility of herbage by sheep.** *J. Brit. Grassland Soc.*, 1955, 10, 19-26. [Grassland Res. Inst., Hurley, Berks.]

For methods see Absts. 3834, 5320, Vol. 24.

Six experiments with 6 or more animals all showed an increase in the percentage of dry matter digested when sheep were given frozen herbage at a level of from 70 to 83 per cent. of that of their full-fed mates. The increase in digestibility ranged from 0.3 to 2.7 per cent., the weighted mean being 1.06 per cent.

J. L. Corbett.

5746

BAILEY, G. L., BALCH, C. C. and MURDOCH, J. C. **The digestibility and feeding value of lucerne/timothy sward ensiled in four ways.** *J. Brit. Grassland Soc.*, 1955, 10, 27-34. [Nat. Inst. Res. Dairying, Univ. Reading.]

A lucerne and timothy sward was ensiled with the addition of either glycolic acid, molasses or barley meal, or after wilting without additions. Gross chemical composition and digestibility of the silages were similar except that wilting raised the dry matter percentage of the product from approximately 22 to 36, and reduced digestibility of the protein by 10 per cent., probably a result of overheating. A total of 24 Shorthorn, Guernsey and Friesian yearling heifers were fed individually on hay and the silages in different proportions, the relative feeding values of the silages for growth being calculated from equations based on the weights of feeds consumed, liveweight and growth rate. This technique was shown to provide a measure of the nutritive value of individual feeds in mixed rations.—J. L. Corbett.

5747

COOK, C. W., STODDART, L. A. and HARRIS, L. E. **The nutritive value of winter range plants in the Great Basin as determined with digestion trials with sheep.** *Utah Agric. Exp. Stat. Bull.* No. 372, September, 1954, pp. 56.

The winter forage of the range of the Great Basin region of Utah consists mainly of browse of the saltbush and sagebush types with some grasses and a few forbs. In some areas grass predominates. Sheep are usually wintered on the range without supplement. Feeding and digestibility trials from 1946 to 1953 showed that the range provided keep borderline or low in digestible protein and metabolisable energy and nearly always deficient in P. When only moderate grazing was allowed utilisation and digestibility were good, but heavy grazing decreased both. Browse supplied abundant carotene. On areas with a majority of

browse, supplements supplying energy were necessary, and in areas where there was more grass than browse a protein supplement was necessary. Where the browse was mainly of the saltbush type an intermediate supplement was best. The forage plants are described and illustrated.—T. D. Bell.

5748

SCHNEIDER, W. **Verdauungsversuche mit Sepa-Patent-Schnitzel. [Digestion experiments with Sepa-patent slices.]** *Ztschr. Tierernährung Futtermittelk.*, 1955, 10, 56-59. [Inst. Tierernährungslehre, Landw. Hochschule, Stuttgart, Hohenheim.]

In digestibility trials with wethers ordinary dried beet pulp was compared with 2 samples mineralised with molasses waste [*Vorscheideschlamm*]. There was little difference in digestibility, but the mineralised slices had a Ca : P ratio of 17 : 1 and it is considered desirable that P should be added before the Sepa slices could be recommended.

D. Duncan.

5749

NORDFELDT, S. (with RUUDVERE, A., TOIGER, E. and LAGERWALL, P.) **Digestibility experiments with pigs.** *Kgl. Landbrukshögsk. Ann.*, 1954, 21, 1-29. [Nat. Animal Exp. Stat., Uppsala.]

The results of 120 original experiments and 1400 experiments reported between 1900 and 1951 on digestibility of different feeds by pigs were examined. The pigs used were considered in groups by weight, under 100 kg., 100 to 180 kg. and over 180 kg. It was shown that the percentage digestibility of organic matter, N-free extract, protein and crude fibre increased directly with the liveweight of the pig. Ether extract was digested less efficiently as liveweight increased. The percentage of crude fibre affected the digestibility of the other components of the feed. This effect depended on the composition of the fibre and varied from feed to feed. Some feeds vary greatly in the chemical composition of the fibre, and some are relatively stable, a fact which must be kept in mind when calculating digestibilities from formulae. The effect of crude fibre on the digestibility of the feed also varies to some extent with the liveweight of the pig.—T. D. Bell.

5750

BOLTON, W. **The digestibility of the carbohydrate complex of barley, wheat and maize by adult fowls.** *J. Agric. Sci.*, 1955, 46, 119-122. [Poultry Res. Centre, W. Mains Rd., Edinburgh 9.]

Five samples of bran, oats, barley, wheat and maize contained 51, 57, 69, 65 and 69 per cent. of N-free extractives. Digestibility trials with adult Brown Leghorn cocks showed that these materials contained 28, 42, 64, 54 and 66 per cent. of

N.A. and R., October 1955

digestible carbohydrates, so that the ratio N-free extractives to digestible carbohydrate varied widely. Further analysis showed that the materials contained 22, 35, 59, 51 and 62 per cent. of "available" carbohydrate (defined as starch and sugar, expressed as starch) all of which was digestible; and these figures represented 81, 83, 92, 93, and 95 per cent., respectively, of those obtained for total digestible carbohydrate in the digestibility trials. Some of the difference was accounted for by digestible pentosans, which formed from 2 to 4 per cent. of each sample.—K. J. Carpenter.

5751

DYMSZA, H., BOUCHER, R. V. and McCARTNEY, M. G. Investigation of crude fiber digestion in 12-week-old turkeys. *Poultry Sci.*, 1955, 34, 240-242. [Dept. Agric. Biol. Chem., Pennsylvania State Univ., University Park.]

Turkeys, 12 weeks old, were caged individually and fed on rations containing 5, 10 or 15 per cent. of crude fibre. These levels were obtained by varying the proportions of oat hulls, maize meal and soya bean oilmeal in the 3 rations, which contained the same levels of animal protein and vitamin supplements.

In a 5-day digestibility trial the percentage of the crude fibre in the 3 rations that appeared to be digested were 1.0, 2.1 and 2.7 per cent., respectively. These are considered to show a negligible digestion of crude fibre by turkeys of this age.

K. J. Carpenter.

5752

DOWE, T. W., MATSUSHIMA, J. and ARTHAUD, V. The effects of the corn-alfalfa hay ratio on the digestibility of the different nutrients by cattle. *J. Animal Sci.*, 1955, 14, 340-349. [Univ. Nebraska.]

The digestibility of the dry matter, crude protein, crude fibre, ether extract and N-free extract of rations in which the ratios of maize to alfalfa hay were 1:1; 2:1; 3:1; 4:1 and 5:1 was estimated in a series of digestibility trials with yearling Aberdeen-Angus or Hereford bulls and Hereford steer calves. As the amount of maize in the rations increased the amounts of dry matter, crude protein and N-free extract in the faeces also increased. Statistical analysis of the data showed that the apparent digestibilities of the nutrients did not differ significantly between one ration and another.—J. N. Aitken.

5753

MACINTYRE, T. M. The digestibility of dried ground seaweed meal by the laying hen. *Canad. J. Agric. Sci.*, 1955, 35, 168-174. [Exp. Farm, Nappan, N.S.]

The digestibility of *Fucus vesiculosus* and *Ascophyllum nodosum*, the species of seaweed most

commonly found on the coast of Nova Scotia, was investigated in trials in 1952, 1953 and 1954. Six 1-year-old Barred Plymouth Rock laying hens were used in each trial, and the trials lasted for 4 to 8 days, preceded by a preliminary period of 4 days. Since the birds would not accept seaweed meal alone it had to be mixed, at a level of 10 to 50 per cent., with a basal ration. In the first year it was given dry, and subsequently as a wet mash. In all the trials the addition of seaweed meal depressed the digestibility of all constituents of the ration except ether extract in 2 cases. The digestibility of the seaweeds, calculated by difference, was also low, and sometimes, for some constituents, negative.—T. D. Bell.

5754

BLACK, W. A. P. Seaweed in animal footstuffs. 1. Availability and composition. 2. Feeding and digestibility trials. *Agriculture, J. Minist. Agric. Engl.*, 1955, 62, 12-15; 57-62. [Inst. Seaweed Res., Inveresk, Midlothian.]

A review.

5755

RICE, E. E., MONE, P. E., GRAY, R. E., HOLLEMAN, R. G. (Jr.) and BEUK, J. F. Use of fats in animal feeds. The value of fat as a feedstuff. *J. Amer. Oil Chem. Soc.*, 1954, 31, 56-59. [Nutrit. Biochem. Res. Div., Res. Labs., Swift and Co., Chicago, Ill.]

The results of trials with poultry and pigs are presented. They show that when 3 to 14 per cent. of fat was added to a control ration less feed per lb. liveweight increase was required. Other improvements due to the addition of fat, such as easier handling of dusty feeds, better appearance and palatability, and easier pelleting, and possible difficulties in commercial practice are discussed.

T. D. Bell.

5756

DIJKSTRA, N. D. De voederwaarde van snijrogge. [Feeding value of green rye.] *Landbouwk. Tijdschr.*, 1955, 67, 201-206. [Rijkslandbouwproefstat., Hoorn.] English summary.

Green rye is a traditional crop on sand in the Netherlands, for either spring or autumn feeding. Digestibility was estimated in 1888 by Frear *et al.* (*Pennsylvania Agric. Exp. Annu. Rep.*) and possibly by other, unidentified, workers. The tests reported here were made on 3 wethers, fed on green rye alone, 0.77 to 0.79 kg. per head daily. There were 4 experiments in April and May 1954, a dry spring. Protein and its digestibility decreased; fibre, which was much less than reported in the literature, roughly 17 to 23 per cent. of dry matter as compared with 30 to 36 per cent., also was slightly less digestible from the first to the last test. Digestible true protein and starch

equivalent for the 4 tests were on the average, per 100 g. dry matter, 9.80, 8.17, 5.34 and 3.54 and 72.2, 73.4, 71.1 and 68.7. Digestible true protein was equivalent to digestible crude protein less 0.91, the amides present.—I. Leitch.

5757

ROGERSON, A. **Nutritive value of sunflower heads.** *E. African Agric. J.*, 1955, 20, 189-190. [Joint Animal Indust. Div., E. African Agric. Forest. Res. Organiz.]

Ground sunflower heads which had lost about 30 per cent. of their seeds before grinding had the following percentage composition and, in brackets, digestibility coefficients: crude protein 14.63 (74.3); ether extract 7.19 (90.2); crude fibre 24.07 (43.0); N-free extract 45.54 (65.5); true protein 12.58 (83.5). The calculated starch equivalent was 52.1 and the protein equivalent 10.7. The digestibility trials were made on sheep.

J. S. Thomson.

5758

ROGERSON, A. **Nutritive value of green *Indigofera subulata* herbage.** *East African Agric. J.*, 1955, 20, 240. [Animal Indust. Div., E. African Agric. Forest. Res. Organiz.]

Some species of the genus *Indigofera* (legume) are poisonous to livestock and an experiment with sheep was made to find out whether *Indigofera subulata*, a promising species in Kenya and Southern Rhodesia, was poisonous. Two sheep were fed for 20 days on this legume as sole diet; apart from some scouring, no ill effect was noted. The composition, on a dry matter basis, was crude protein 16.78, ether extract 1.06, crude fibre 31.81, N-free extract 40.85 and true protein 13.47 per cent. Composition and digestibility data showed that this species compared favourably with the temperate legumes vetch and sainfoin.

J. S. Thomson.

5759

FRENCH, M. H. **Earth-eating and the mineral needs of livestock.** *E. African Agric. J.*, 1955, 20, 168-175. [Joint Animal Indust. Div., E. African Agric. Forest. Res. Organiz.]

The history of the development of knowledge about the mineral requirements of livestock and feeding habits which may be connected with them is described. No theory about the reasons for geophagia or other forms of depraved appetite fits all the facts, since none explains the ingestion of excesses, or of poisonous elements, or the refusal of one form of an essential element and acceptance of another. It is also hard to accept the belief that animals are capable of knowing their requirements and of satisfying them when man is not. The functions of minerals and the results of deficiencies or excesses are described.

T. D. Bell.

5760

ROGERSON, A. **Nutritive values of locally prepared cottonseed and linseed cakes.** *East African Agric. J.*, 1955, 20, 245-246. [Animal Indust. Div., E. African Agric. Forest. Res. Organiz.]

Samples of locally prepared cottonseed and linseed cakes were analysed and digestibility trials were made with sheep. The cottonseed cake had a high crude fibre content, 17.58 per cent. in the dry matter, about twice the normal amount, showing that the hulls had not been completely removed during decortication. Digestibility data were similar to those quoted by Woodman except for crude fibre, where a value of 100 per cent. was obtained, a figure differing widely from that of 28 per cent. quoted by Woodman.

Data for linseed cake were similar to quoted values for British samples except for a somewhat higher oil content and higher starch equivalent.

It is concluded that both the locally prepared products are valuable concentrates for stock.

J. S. Thomson.

5761

ROGERSON, A. **Nutritive value of coffee hulls.** *East African Agric. J.*, 1955, 20, 254-255. [Animal Indust. Div., E. African Agric. Forest. Res. Organiz.]

The chemical composition of 2 samples of coffee hulls was: crude protein 10.17, 9.25; ether extract 1.58, 2.02; crude fibre 35.46, 29.74; N-free extract 45.68, 51.46; true protein 7.29, 7.72. Digestibility values, obtained with sheep, were all low, that of crude protein being only 13.5 and 7.0 per cent. for the 2 samples. The calculated protein equivalent was 0.7 per cent. The coffee hulls were palatable, but cannot be regarded as a concentrate.—J. S. Thomson.

5762

MAHADEVAN, V. and SATYANARAYANA RAO, K. **Nutritive value of green manure crops. 1. *Sesbania speciosa*.** *Indian Vet. J.*, 1954-55, 31, 83-87. [Dept. Animal Nutrit., Madras Vet. Coll.]

Leaves and stalks of *Sesbania speciosa*, a leguminous plant used for green manure in the United States and more recently in India, had the following percentage composition on a dry matter basis when cut at 5 months: crude protein 24.7, 10.9; ether extract 9.0, 6.9; crude fibre 16.2, 29.75; N-free extract 43.1, 43.9; total ash 7.1, 8.5; silica 0.8, 3.8; Ca 0.8, 1.25; P 0.3, 0.2. These figures suggested that it might be a useful fodder if the Ca:P ratio was corrected; but cattle would not eat it, nor would guineapigs when it was mixed with other greens, and when other greens were not given they consumed little *Sesbania speciosa* or

N.A. and R., October 1955

S. grandiflora and lost weight. It is concluded that *S. speciosa* is unlikely to be useful for fodder.

W. M. Deans.

5763

MAHADDEVAN, V. The composition and nutritive value of tobacco (*Nicotina tabacum* L.) seed cake or meal. *Indian Vet. J.*, 1954-55, 31, 280-282. [Dept. Animal Nutrit., Madras Vet. Coll.]

A sample of tobacco seed cake had the following percentage composition : moisture 7.1, crude protein 31.5, ether extract 12.3, crude fibre 21.5, N-free extract 17.7, total ash 9.9, silica 4.4, Ca 0.33, P 0.87. The oil content was several times that reported from Italy by Maymone and Tiberio (Abst. 5057, Vol. 18). With their results for digestibility coefficients, the total digestible nutrient content was calculated to be about 56. Tobacco seed cake is considered likely to be a useful feedingstuff.—W. M. Deans.

5764

WELLS, F. B. A note on jojoba bean meal—a potential feed. *Cereal Chem.*, 1955, 32, 157-159. [Labs., Bloomfield Coll. and Seminary, Bloomfield, N.J.]

Jojoba (*Simmondsia californica*) is an evergreen shrub growing wild in southern California, Arizona and western Mexico. The seed is eaten by rodents. It contains about 45 per cent. oils, and after extraction the meal had 31 per cent. protein and 28 per cent. carbohydrates. Small quantities ingested by the author did not have any harmful effect, though the taste is bitter. In view of the favourable chemical analysis, trials using the meal as a feed for stock seem desirable.—T. D. Bell.

5765

DLEKSTRA, N. D. De voederwaarde van natte pulp, afkomstig van continue diffusie. [Feeding value of wet pulp from the continuous diffusion process.] *Landbouwk. Tijdschr.*, 1955, 67, 207-215. [Rijkslandbouwraproefstat., Hoorn.] English summary.

In continuation of a study by the author (Abst. 5150, Vol. 23) in which beet pulp obtained by a discontinuous diffusion process after pre-treatment with SO_2 was compared with that from the normal warm diffusion, these types were tested again with a third from a continuous warm process. Analysis are reported in full for the pulp as produced and for silage made from it and digestibility data for 3 wethers for the silage.

The silage from the cold process was the only one without butyric acid. The structure of the beet was better preserved and so the dry matter content was higher and the losses less. The digestibility also was much higher, 82 per cent. of organic

matter as compared with 54 and 52 for the warm-process silages. Cold-process silage had more than twice as much digestible protein and a starch equivalent half as high again as the others.

I. Leitch.

5766

PARINI, V. P. Belkogo-Vitaminayna pasta. [Protein and vitamin paste.] *Nauka i Zhizn'*, 1953, No. 11, 35.

The pressed filtered juice of green plants is heated to 80° to 100° [C.] The protein coagulates and floats to the surface; excess moisture is then squeezed out, producing a green curd-like mass with 60 per cent. protein and more than 10 per cent. fat, and a carotene content 50 to 100 times that of hay. This paste can be used either fresh or preserved in barrels with 10 to 15 per cent. minced sugar beet. In this form it can be kept for years. For calves it can replace 50 per cent. of the milk and can be given from birth. Egg laying is increased when poultry are given the paste.—H. Scherbatoff.

5767

PRESTHEGGE, K. Ensilert fiskeavfall i fôringen. [Ensiled fish waste in livestock feeding.] *Ny Jord*, 1954, 40, No. 4, 97-102.

The composition of fish waste, including fish not usually marketed as food, is discussed. Ensiling with formic acid is recommended and quantities of silage suitable for milk cows, pigs and other farm animals are discussed.—I. Leitch.

5768

D'YAKOV, A. B. Shire ispol'zovat' rybnye ot-khody. [The wider use of fish waste.] *Karakul. Zverovodstvo*, 1954, 7, No. 5, 42-47. [Moscow Fur Inst.]

Better use of fish waste is recommended.

Feeding pigs on "graks" (boiled cod liver with partial removal of fat) and stearin instead of fish oil gave good results. When seal flesh formed 80 per cent. of the rations of polar foxes and mink, production was higher than ever before both in healthy cubs and in fur; seal flesh was considerably cheaper than horse flesh. If fresh fish is given, yeast and liver should be added to the ration, since fresh fish, except cod and certain other species, inactivates the vitamin B_1 in other foods.

"Graks" contains 400 to 600 I.U. vitamin A, moisture 54 to 75, fat 14.2 to 31.7, protein 8.4 to 12.1, ash 0.8 to 0.9 per cent.—H. Scherbatoff.

5769

5770

DUCKWORTH, J. The value of certain agricultural, marine and industrial products and by-products in livestock feeding. *J. Sci. Food Agric.*, 1955, 6, 177-185; 240-250. [Rowett Res. Inst., Bucksburn, Aberdeenshire.]

5771

VOISIN, A. Die vier Grundgesetze einer rationellen Weidewirtschaft. [The four basic laws of rational pasture management.] *Mitt. Deutsch. Landwirtschaft.-Gesellsch.*, 1955, No. 1, 2, 3, pp. 5. [Dieppe.]

An article on the advantages of rotational grazing. The author's 4 basic laws are: (1) the cattle that need the best feed should get grass when it is from 10 to 15 cm. high; (2) the same group of beasts should not be on the same ground for more than 3 days, and only 1 day is better; (3) the grass should be used at the time of maximum reserves in the roots; (4) the same ground should not be in use for more than 4 or at most 6 days at a time, so that the grass does not grow long enough to be grazed twice in rapid succession. Supplying green fodder does not prevent cows cropping the young grass. In Normandy the necessary resting period ranges from 14 to 18 days in May to 40 to 60 in autumn.—W. M. Deans.

5772

KULAEV, V. B. and YAKHONTOV, N. S. Sudan-skaya trave—tsennaya kormovaya kul'tura. [Sudan grasses, a valuable fodder crop.] *Konevodstvo*, 1955, 25, No. 1, 27-28. [VNIIEK.]

Sudan grass, a new crop for the experimental stud farm of the VNIIEK, did well on the local grey podzolic soils and recovered quickly after being used as pasture. The yield of hay was 135 to 146 tseentners per ha. (2733 to 2955 kg. per acre), being almost 6 times greater than that of vetches and oats. Both cattle and horses preferred Sudan grass to vetches and oats. The chemical composition of Sudan grass was: protein 10 to 14, fat 2 to 4, carbohydrate 40 to 45, fibre 28 to 29, ash 8 per cent.—H. Scherbatoff.

5773

MARCHENKO, I. Novaya kormovaya kul'tura. [A new feed crop.] *Nauka i Zhizn'*, 1954, 21, No. 12, 41.

A hybrid of Jerusalem artichoke and sunflower is described. The tops, which are used for silage, contain 12 to 15 per cent. sugar and up to 3 per cent. digestible protein. The tubers contain 2.85 per cent. ash with a high Fe content. One hundred kg. of tubers yields 22.8 feed units. The stems contain 106.8 mg. carotene per kg., which is 2 to 3 times higher than in either sunflowers or Jerusalem

artichokes. Yields were for the hybrid 23,190 feed units per ha., for sunflowers 5720 units and for maize and potatoes 6550 and 7030 units per ha. Both the tubers and silage made from the stems were eaten readily by pigs. The tubers are recommended as a succulent fodder for early spring feeding.—H. Scherbatoff.

PRENDERGAST, J. J. and BRADY, J. J. Animal output of reseeded grassland. 1. The effects of strain of seed on the total output of grassland over a four-year period, and the effects of strain of seed and nitrogen treatment on annual output. *J. Brit. Grassland Soc.*, 1955, 10, 169-176. [Dept. Agric., Dublin.]

Trials were made from 1949 to 1953 to compare plots sown with Aberystwyth and commercial strains of grasses and clovers in a Cocker Park mixture. In the last year half of each received 4 dressings of Nitro-Chalk, totalling 7 cwt. per acre, and the other half got no nitrogen dressing. The plots were rotationally grazed by sheep and bullocks and cut for silage.

Liveweight gains per acre in the 4 years were 2138 lb. for Aberystwyth and 2219 lb. for commercial pastures, with 3.75 and 3.33 tons of cut grass, and estimated starch equivalent outputs were 146.01 and 146.57 cwt. The application of Nitro-Chalk in the last year increased liveweight gain per acre from 565 to 701 lb. on the Aberystwyth and from 548 to 700 lb. on the commercial pasture.—T. D. Bell.

5775

BRITISH GRASSLAND SOCIETY. The assessment and recording of the utilized output of grassland. *J. Brit. Grassland Soc.*, 1955, 10, 67-79.

This is a report by a sub-committee of the British Grassland Society. The different species and categories of grazing animals are classified according to their energy requirements. Suggestions are made for the evaluation of conserved grass products. It is stressed that grassland output estimated from these figures by using the record forms devised are of value primarily for management comparisons, rather than for estimates of the absolute scale of production achieved.

BAILEY, G. L. and BROSTER, W. H. The fragmentation losses of lucerne hay due to handling. *J. Brit. Grassland Soc.*, 1955, 10, 191-192. [Nat. Inst. Res. Dairying, Univ. Reading, Shinfield.]

During the handling of baled lucerne hay there is liable to be a loss of brittle leaf fragments amounting to about 8 per cent. of the remaining stalky hay. This fraction is much richer in crude protein (20.9 per cent.) than the stalky hay (10.4 per cent.), and much lower in fibre, 19.8 per cent. as against 36.3 per cent. This might affect the results of feeding trials according to the amount of each fraction fed.—J. S. Thomson.

5780

NOVIKOVA, A. E. Ultraioletovoe obluhenie zhivotnykh. [Ultraviolet irradiation of livestock.] *Nauka i Zhizn'*, 1954, 21, No. 3, 36.

By the use of specially constructed equipment [not described] it was possible to treat piglets with ultraviolet light under ordinary conditions on a pig breeding farm. Each of 1100 piglets showed an increase of 9 kg. more over a period of 4 months than the piglets in the untreated group. Exposure was for 8 to 10 min. daily.

Treatment of hens during the autumn and winter increased egg production by more than 30 per cent. Young animals not only made rapid growth but also acquired immunity to disease.

DAVIS, H. P. Relazione fra il peso vivo e sette altre misurazioni del corpo di bovine Holstein Friesian alla nascita e all'età di 6, 12, 18 e

Vol. 25, No. 4

24 mesi. [Relations between liveweight and seven other body measurements in Holstein Friesian cattle at birth and at the age of 6, 12, 18 and 24 months.] *Zootec. Vet.*, 1955, 10, 72-73. [Univ. Nebraska, Lincoln.]

Liveweight at birth and at 6, 12, 18 and 24 months of age of 150 Holstein Friesian heifers was measured. The correlations between these weights and length of body, length of rump, height at shoulder, height at hips, chest girth, depth of chest and width of pin bones were calculated. Significant positive correlations of from 0.39 to 0.84 were found for all measurements tested.—T. D. Bell.

5788

DE FRANCISCIS, G. Il fosfato bicalcico quale integrante dell'alimentazione del bestiame. [Dicalcium phosphate as supplement in the feeding of cattle.] *Bol. Soc. ital. Biol. sper.*, 1953, **29**, 1794-1796. [Ist. Fisiol. Vet., Univ. Naples.]

Of 4 calves fed on a normal diet, 2 were given in addition daily for 4 months 15 g. dicalcium phosphate. They were weighed and measured every 2 weeks. In the 4 months the untreated calves gained 68.5 and 72 kg.; those given phosphate gained 76 and 76.5 kg., and all their other measurements also were slightly superior.—E. M. Hume.

5789

HAWKINS, G. E. (Jr.), WISE, G. H., MATRONE, G., WATUGH, R. K. and LOTT, W. L. Manganese in the nutrition of young dairy cattle fed different levels of calcium and phosphorus. *J. Dairy Sci.*, 1955, **38**, 536-547. [Dept. Animal Indust., N. Carolina Agric. Exp. Stat., Raleigh.]

Fifteen Holstein, Jersey and Guernsey calves were divided into 5 groups. The control group was given rations normally used for young calves. After being suckled for 3 days the experimental groups got a synthetic diet with only 1 p.p.m. Mn, the same diet supplemented with 50 p.p.m. Mn, 5 per cent. monocalcium phosphate or both. Weight gains were recorded, and blood samples were analysed for Mn in whole blood and Ca, inorganic P, alkaline phosphatase and Mg in serum. Post-mortem examinations were made of all the experimental calves.

The growth rate of control calves was superior to that of all experimental calves. The Mn supplement did not affect serum Ca, inorganic P or alkaline phosphatase activity, but serum Mg was depressed, more when Ca and P were given also. Mn values in whole blood were increased by the supplement of this element, and this was partly counteracted by the Ca and P supplement. All the experimental calves died within 382 days, showing non-specific clinical signs which are described. Mn prolonged the life span, and the signs were not observed till later in these calves. Signs appeared first in the calves getting Ca and P only, and these animals died earliest. Death was thought to be due to general undernutrition, not to a specific deficiency. At post-mortem exam-

ination calcified lesions were found in the pulmonary and cardio-vascular systems of all the calves which had been given supplements.

WING, J. M. Effect of orotic acid and methionine supplementation on feed consumption and growth of young dairy calves. *J. Dairy Sci.*, 1955, **38**, 504-507. [Dept. Dairy Sci., Florida Agric. Exp. Stat., Gainesville.]

A pilot investigation with 40 newborn Jersey calves showed that supplementation with equal amounts of methionine and orotic acid dispersed in milk at the rate of 440 mg. per 100 lb. bodyweight significantly increased liveweight gain compared with controls. In a second experiment with 2 groups of 6 calves the supplements were administered in a gelatine capsule directly into the reticulo-rumen cavity. Highly significant differences in favour of the supplemented group were obtained in rate of liveweight gain and in efficiency of feed utilisation.—J. N. Aitken.

5791

PRITCHARD, G. I., NEWLANDER, J. A. and RIDDELL, W. H. Aureomycin effects—growth and digestibility studies with identical twin calves. *J. Animal Sci.*, 1955, **14**, 336-339. [Vermont Agric. Exp. Stat.]

Four pairs of 1-week-old identical twin male calves were used in an experiment of 7 weeks' duration. One calf of each pair served as a control; the other was given aureomycin in milk, 30 mg. per 100 lb. bodyweight daily. All calves received hay to appetite and up to 4 lb. of a concentrated mixture daily. Treatment significantly increased rate of gain and efficiency of feed utilisation. A digestibility trial was made when the feeding trial ended. There was no significant within-set difference in the digestibility of dry matter, ash, protein, crude fibre, N-free extract or fat.—J. N. Aitken.

5792

LASSITER, C. A., DENTON, T. W. and BASTIN, G. M. The value of certain surfactants and other growth stimulants in the rations of young dairy calves. *J. Dairy Sci.*, 1955, **38**, 407-415. [Kentucky Agric. Exp. Stat., Lexington.]

In the first experiment 6 groups of 6 Jersey and Holstein calves were used. They were allowed colostrum for the first 2 days and were then fed for 84 days on a calf starter and hay and grain to appetite. The calf starter contained linseed oil-meal and had 18 per cent. protein. Whole milk was given for the first 7 weeks. Group 1 got no supplement. Group 2 had aureomycin, group 3 Ethomid C/15, group 4 Arquad HT, group 5 Ethomid C/15 and Arquad HT and group 6 Ethomid C/15 and aureomycin. Ethomid C/15 is

N.A. and R., October 1955

a preparation of polyoxyethylene cocoamide, a non-ionic surface-active substance; Arquad HT is trimethyl octadecyl ammonium chloride, a cationic surface-active substance. Increases in growth rate over control, group 1, significant at the 5 per cent. level, were produced by all the supplements. There were also increases in chest girth and height at withers, but these were not analysed statistically. Efficiency of feed utilisation was improved, but not significantly so. Serious scouring occurred in group 4.

The second experiment was similar to the first, but there were 8 calves in each group, and the calf starter had soya bean oilmeal instead of linseed oilmeal, raising the protein content to 21 per cent. Groups 1 to 3 and 6 were treated as in the first experiment; group 4 was given a cationic surface-acting substance, trimethylalkylammonium stearate, and group 5 had Arquad HT at a lower level than previously. There was no significant difference in growth rates between groups in this experiments. The surface-active substances did not stimulate growth or improve efficiency, and group 6 was no better than group 2, contrary to the findings in the first experiment. Scouring was a problem only in group 4. Representative carcasses from each group showed no abnormality. The results of these 2 experiments would not seem to justify the use of surface-active substances to stimulate growth in young calves.—T. D. Bell.

5793

HOMB, T. and BREIERM K. (with NYGAARD, J., EVJU, R. and HENRICHSEN, TH.) Føring av kalver uten flytende skummet melk. [Feeding calves without liquid skimmed milk.] *Samvirke*, 1954, 49, 548-555.

Fifteen calves bought in the market were used, in 3 groups of 5, to compare the results of rearing with skimmed milk, with dried reconstituted skimmed milk and with a calf starter [not further described]. All groups did equally well but fresh skimmed milk was the cheapest.—I. Leitch.

5794

HAWKINS, G. E. (JR.) Consumption and digestibility of *Lespedeza sericea* hay and alfalfa hay plus gallotannin. *J. Dairy Sci.*, 1955, 38, 237-243. [Dept. Dairy Husb., Alabama Polytech. Inst., Auburn.]

Dairy calves, 6 months old, were used in palatability and digestibility trials with hays of sericea lespedeza (*Lespedeza cuneata*) and alfalfa with added gallotannin. Alfalfa hay alone was used as the control ration. Chemical analysis showed the lespedeza hay to have much less crude protein and more lignin than the alfalfa hay. The experimental rations were equal in tannin, and had more than the control ration, but the lespedeza tannin

was of the catechol type and the alfalfa tannin of the gallo type.

In the palatability trial less total dry matter and water were consumed on the lespedeza hay, and the calves lost weight. Digestibility of dry matter and of crude protein of lespedeza hay was less than that of either control or experimental alfalfa hay.

Tannin affects palatability by its astringent taste and digestibility by precipitation of protein as insoluble tannates, properties possessed by both forms of tannin found in the analysis, and the low values found for lespedeza hay were not, therefore, thought to be due to its high tannin content, since this was the same in the experimental alfalfa ration. It may be that some of the tannin in the lespedeza is already combined with some of the protein in the plant as insoluble tannate, or that tannin added to the alfalfa ration was inactivated in the upper part of the gut before it could affect the protein. The more likely reason for the low values was the higher lignin content. The calves' loss of weight could be ascribed to the low feed intake.—T. D. Bell.

5795

MUSGRAVE, S. D., WILLIAMS, J. B., NORTON, C. L. and GALLOP, W. D. Alfalfa vs. prairie hay for dairy calves. *J. Dairy Sci.*, 1955, 38, 416-419. [Dept. Dairying, Oklahoma Agric. and Mech. Coll., Stillwater.]

Two trials, one in summer, one in winter, were made to compare alfalfa and prairie hays, given from 2 days or from 8 weeks of age to dairy calves. All calves were given a calf starter and whole milk after suckling for 2 days. The trials lasted 16 weeks. In each trial both groups getting alfalfa required less total digestible nutrients per lb. live-weight gain than those getting prairie hay. Calves in the winter trial ate more starter, required less total digestible nutrients per lb. increase in weight, gained more and weighed more at 16 weeks of age than those in the summer trial. The carotene intake of the calves in the summer trial was greater than that of the calves in the winter trial and was greater for the alfalfa than for the prairie hay groups, but there was no relation between vitamin A and carotene in plasma and treatment or season. T. D. Bell.

5796

PRESTON, T. R. The artificial rearing of calves on pasture grass. *J. King's Coll. Agric. Soc., Univ. Durham*, 1953/54, 9, 24-28.

Indoor rearing of young calves was compared with outdoor rearing in a pilot experiment with 2 groups of 3 calves each. Both groups received 35 gal. whole milk up to weaning. The indoor calves were reared in the normal way and received up to 3 lb. concentrates per head daily and hay to

appetite. From a few days after birth the outdoor calves strip-grazed a poor quality pasture which had not previously been grazed by cattle. Grazing was continued throughout the summer. During the subsequent winter both groups were housed and given normal rations. By the end of the second summer the bodyweights of the outdoor calves were substantially greater than those of the calves reared indoors. Rate of gain up to weaning was the same for both groups.

A similar trial was made in the wet summer of 1954; 7 pairs of dizygous twins and 3 pairs of half-sibs were divided between the 2 treatments. In this experiment the outdoor calves were folded round 6 permanent grass paddocks instead of being grazed exclusively on clean ground. Bodyweights of the outdoor calves declined after weaning. It was concluded that the poor performance of the outdoor calves in the 1954 trial was due largely to weather and worm burden.

5797

POLYAKOV, N. F. Silosnyi sok. [Silage juice.] *Nauka i Zhizn'*, 1954, 21, No. 3, 34. [Altai Reg. Sci. Res. Vet. Exp. Stat.]

To avoid vitamin deficiency in newborn calves in winter they were given silage juice from birth as a vitamin supplement to colostrum or milk. Silage of maize, sugar beet tops, Sudan grass or sunflower with green oats was used. The calves were given 100 to 300 g. 3 to 4 times daily. All signs of vitamin deficiency in calves disappeared in 3 to 5 days and there was a sharp drop in fresh cases. In 2 weeks the average daily gain of weight was 100 to 175 g. more in the calves getting silage juice than in the controls.

Over a litre of juice was obtained from 1 kg. silage. A litre of sunflower and green oats silage juice contained 18 to 34 mg. carotene and 35 per cent. lactic acid as well as other substances essential for the organism.

To obtain satisfactory silage juice, the silage should contain not less than 20 mg. carotene per kg. and have a moisture content of not less than 65 to 75 per cent. After the silage has been cut up it is heated at a temperature of 70° to 80° [C.], for 30 to 40 min. and the juice is squeezed out in a press. The residue is given to cattle.

H. Scherbatoff.

ANGUS, R. C. and BARR, W. L. An appraisal of research literature dealing with loose and conventional dairy cattle housing. A review. *J. Dairy Sci.*, 1955, 38, 391-406. [Dept. Agric. Econ., Pennsylvania State Univ., University Park.]

5799

NATIONAL RESEARCH COUNCIL, U.S.A., COMMITTEE ON ANIMAL NUTRITION. *Recom-*

mended nutrient allowances for domestic animals. 4. Recommended nutrient allowances for beef cattle. Revised December 1950, pp. 37.

Recommended allowances of digestible protein, total digestible nutrients, Ca, P and carotene are set out for growth, fattening, reproduction, pregnancy and nursing of beef cattle. The recommendations are based on the literature, to which there are 113 references, mostly American. Vitamin and trace mineral requirements are discussed and signs of nutritional deficiencies described. Tables of average digestible proteins and total digestible nutrients of common feeds are presented, and suitable rations are suggested. The need for supplements for cattle on the range is discussed.—T. D. Bell.

5800

MACDONALD, M. A. and BOGART, R. Relationship between rate and efficiency of gain and type in breeding beef cattle. *N.Z. J. Sci. Technol.*, [A], 1955, 36, 460-469. [Dept. Animal Husbandry, Oregon State Coll., Corvallis.]

Birthweight, weaning weight, rate and efficiency of liveweight increase (the latter from weaning to 800 lb. only) and type score by visual appraisal at 500 lb. and 800 lb. liveweight of 42 purebred Hereford and Aberdeen-Angus bulls and heifers were studied. All animals were reared with their dams on irrigated pasture till weaning at about 450 lb. liveweight, and were then fed to appetite in stalls. The type scores were higher at the heavier weight, but repeatability was low and the earlier appraisal could not be used to predict the later. Neither type score was related to any other features studied. There was a positive correlation between birthweight and rate of gain from weaning to slaughter, but no correlation between the latter and the earlier rate of gain from birth to weaning. It was concluded that information on production as well as visual appraisal is necessary for the selection of beef bulls.—T. D. Bell.

5801

HITCHCOCK, G. H., SAWYER, W. A., BOGART, R. and CALVIN, L. Rate and efficiency of gains in beef cattle. 3. Factors affecting weight and effectiveness of selection for gains in weight. *Oregon Agric. Exp. Stat. Tech. Bull.* No. 34, March 1955, pp. 22.

Data for this study were collected from a Hereford herd reared under range conditions. The herd was maintained on poor-quality pasture throughout the 13-year-period during which records were taken. Weaning weights based on the records of 722 calves and yearling weights based on the records of 157 cows and their 376 offspring

N.A. and B., October 1955

provided data for statistical analysis. The results showed that mass selection for yearling weight would be effective in the environment in which the cattle were reared. The age of the dam when the offspring was born had little effect on the yearling weight of the offspring. Selection of dams on the basis of corrected yearling weight resulted in differences in birthweights, corrected weaning weights and corrected yearling weights of the offspring. There was no relation between corrected yearling weight of the dam and either the condition or the grade of the offspring. Maximum progress in selection would be obtained either by comparing the performance of animals born in the same year or by ensuring a uniform environment from year to year. The following equation was used in making the corrections:

$$CW = W - bA + bK,$$

where CW was the corrected weight, W the actual weight, A the actual age, K the constant age and b the slope of the regression line. The method of statistical analysis is described in detail.

J. N. Aitken.

5802

MERRIGALLI, A. Ulteriori ricerche su l'alimentazione di vitelle di razza lattifera con limitate quantità di latte e miscela bilanciata asciutta. [Feeding dairy calves with limited amounts of milk and a dry balanced ration.] *Riv. Zootec.*, 1955, 28, 143-148. [Ist. Zootec., Univ. Florence.]

The method is to give as much colostrum as possible for 3 days, then whole milk for 70 days. After the third week a concentrate with 18 to 20 per cent. protein, good quality hay and fresh water to appetite are offered, and the whole milk is systematically reduced, so that none is given after 70 days. Two dairy calves were reared on this system. Owing to circumstances the experiment could not be started until one of the calves was 7 and the other 4 weeks old, but the system of feeding was applied at the appropriate stage. The calves grew and developed normally, and there was a saving of almost half the milk usually given, and a consequent saving in money.—T. D. Bell.

5803

GROVES, N., STRATTON, P. O., HILSTON, N. W. and PAULES, L. Comparative value of soybean meal, urea, and trace minerals for fattening steers. *Wyoming Agric. Exp. Stat. Memo Circular* No. 49, September 1954, pp. 5.

In a feeding trial lasting 190 days, 5 groups of 10 bullocks of initial liveweight 640 lb. each were used to compare the value of supplements of urea and soya bean meal for fattening. All animals got the same roughage of alfalfa hay and maize silage. The concentrate consisted of ground maize and rolled barley for all groups, and group 1 had 1.12

lb. soya bean meal, group 2, 0.52 lb. soya bean meal and 0.082 lb. urea, group 3 the same with a trace mineral mixture, group 4, 0.249 lb. soya bean meal and 0.118 lb. urea and group 5 the same with a trace-mineral mixture. The average crude protein and total digestible nutrient intakes of all groups were the same.

There was no significant difference between groups in daily liveweight increase, efficiency, cost per lb. liveweight increase calculated on current local prices, dressing percentage or carcass grade. Group 4 showed a slight advantage in liveweight increase and cost per lb. gain, and group 1 had a slightly higher dressing percentage. It was concluded that urea may satisfactorily be used to replace half the soya bean meal on an equivalent crude protein basis in a concentrate for fattening bullocks.—T. D. Bell.

5804

PERRY, T. W., BEESON, W. M., ANDREWS, F. N. and STOB, M. The effect of oral administration of hormones on growth rate and deposition in the carcass of fattening steers. *J. Animal Sci.*, 1955, 14, 329-335. [Dept. Animal Husb., Purdue Univ. Agric. Exp. Stat., Lafayette, Ind.]

Four groups of 10 Hereford steers of 870 lb. liveweight were used. Group 1, control, had no supplement to the basal ration, and the experimental groups, 2, 3 and 4, 10 mg. per head daily of stilboestrol, dienoestrol or hexoestrol, respectively, mixed with the feed. The trial lasted for 123 days. For 5 animals of each experimental group the hormone was discontinued 7 days before slaughter. Daily liveweight increases were 2.33, 2.64, 2.55 and 2.65 lb. for groups 1 to 4, respectively. The experimental groups were also more efficient in feed conversion. Dienoestrol was not as good as the other hormones. The greater part of the improvement due to supplements was in the first 28 days. Carcase grades of group 2 were lower than those of the other groups, but not significantly so. Trials with mice showed that there was no residual hormone in the flesh of the steers. Some enlargement of the teats and raising of the tail head occurred.—T. D. Bell.

5805

MATSUSHIMA, J. and DOWE, T. W. Use of fats in animal feeds. Use of animal fats in rations for beef cattle. *J. Amer. Oil Chem. Soc.*, 1954, 31, 54-55. [Dept. Animal Husb., Univ. Nebraska, Lincoln.]

Three rations were compared in a trial with 3 groups of yearling Hereford steers. Group 1 was given a standard ration consisting of ground shelled maize 17.1, soya bean meal 0.9, brome hay 2.8 lb. and a vitamin A supplement. Group 2

received beef tallow pellets 12.2, ground maize 9.4, and brome hay 2.0 lb. and a vitamin A supplement. The third group was given maize oil pellets 11.9, ground ear maize 9.2, and brome hay 1.8 lb. and a vitamin A supplement. All animals made satisfactory liveweight gains but the gains of the group given maize oil pellets were slightly less than those of the 2 other groups. No digestive disturbance was seen in the steers given beef tallow. Signs of vitamin A deficiency appeared in groups 2 and 3 during the early weeks of the trial but were alleviated when the supplement was increased by 30,000 I.U. to 60,000 I.U. daily. The maximum daily intake of beef tallow reached 3/4 lb.

WILLIAMS, T. E. and DAVIES, W. **Cattle fattening on permanent grass and leys.** *J. Roy. Agric. Soc. Engl.*, 1954, **115**, 98-111. [Grassland Res. Inst., Hurley, Berkshire.]

5807

ALDER, F. E. **Grassland management for meat production.** *J. Brit. Grassland Soc.*, 1955, **10**, 115-125. [Grassland Res. Inst., Hurley, Berks.]

A trial is in progress in which 35.5 acres have been sown in blocks of 3 to 4 acres with 10 different seeds mixtures. The seeds mixtures, the fertilising, and the first 3 years of the trial are described. Bullocks are brought to slaughter at 2 years 9 months old, breeding ewes are maintained and fat lambs produced. Strip and rotational grazing are used, and the plots are cut for silage and hay. No other feed is given. The aim is to extend the grazing season as long as possible and winter grazing, keeping bullocks in store condition, has been attained. Average liveweight increases produced per acre in 1951-52, 1952-53, and 1953-54 were 345, 345 and 313 lb., and average utilised starch equivalents 2770, 2910 and 2720 lb. Average cattle grazing days were 248, 256 and 208, the last figure excluding the use of hay and silage still in hand. A small quantity of concentrates with added minerals is now being given to the ewes immediately before and after lambing, to avoid possible deficiencies.—T. D. Bell.

FAGIOLI, A. **Primo contributo alla soluzione dei problemi tecnici ed economici della produzione di carni bovine pregiate in Umbria con la razza Chianina-Perugina. [Technical and economic problems of high-class beef production in Umbria with Chiana-Perugia cattle.]** *Riv. Zootec.*, 1955, **28**, 114-121.

A series of field trials, started in 1953 and planned to finish in 1956, is being made to find the best age for slaughtering Chiana-Perugia cattle for beef

and to compare heifers with bulls and castrated with entire males. The techniques at the different farms on which the trials are made are being compared, and the economics of the enterprise is being investigated.

One of these trials, with 10 bulls fattened from about 13 months of age for 5 months is described. The beasts were weighed fortnightly and all feeds consumed were accurately recorded, and feed requirements for growth and fattening were calculated. No conclusions can be drawn till the trials are finished, but the results reported show that Chiana-Perugia bulls make good gains at this age, and are more economical than breeds investigated by other workers. They have a high dressing percentage and give first-class carcasses. The high efficiency of feed conversion is probably due to the fact that the bulls put on flesh rather than fat during the trial. The best age for slaughter would probably be between 14 and 18 months, depending on the rate at which individuals mature.

BADRELDIN, A. L. **Dressing out percentage in suckling buffalo veals.** *Indian J. Vet. Sci.*, 1955, **25**, 61-64. [Dept. Animal Breeding, Fac. Agric., Univ. Cairo.]

The average birthweight of 16 male buffalo calves was 90 lb. They were slaughtered after being reared on their mothers' milk, at 30 days of age, when the average liveweight was 134 lb. They required 6 lb. milk per lb. liveweight increase. Another group of 25 calves was slaughtered at 30 to 40 days of age, when the average liveweight was 136 lb. The dressing percentage of all the calves was 66 per cent., and the hide was 8 per cent. of the liveweight. Though it is not profitable to feed veal calves, they must be kept for a month before they can be sold.—T. D. Bell.

KELLY, C. F., BOND, T. E. and ITTNER, N. R. **Water cooling for livestock in hot climates.** *Agric. Eng.*, 1955, **36**, 173-180. [California Agric. Exp. Stat., Davis.]

Trials were made from 1947 to 1954 to show the value of different systems of cooling for beef cattle in a hot climate. Cooling by spraying the animals, by cooling the air by evaporation in shelters enclosed on 3 sides, by cooling the roofs of open shades by evaporation, and by cooling the drinking water were tried. All methods gave better weight

N.A. and R., October 1955

gains and efficiency of feed conversion than were obtained in uncooled controls. The economics of cooling by evaporation in enclosed shelters, showing a small profit, is discussed, but the economics of the other systems needs further investigation.

SANCHO, J., F. Principios científicos en la alimentación del ganado de leche. [Scientific principles in the feeding of dairy cattle.] *Rev. Agric., Costa Rica*, 1955, 27, 25-29; 94-104. [San José.]

5813

BRUMBY, P. J. and HANCOCK, J. The galactopoietic role of growth hormone in dairy cattle. *N.Z. J. Sci. Technol.* [A], 1955, 36, 417-436. [Ruakura Animal Res. Stat., Dept. Agric., Hamilton.]

In the first 2 experiments 9 sets of Jersey type identical twins were used. The twins were divided to form 3 replications of a balanced incomplete block. Thus, within-set comparisons of galactopoietic activity were made between growth hormone and thyrotropic hormone; growth hormone and controls, and thyrotropic hormone and controls. The treated groups received daily subcutaneous injections of 50 mg. of growth hormone or 15 T.S.H. (U.S.P. standard) units of thyrotropic hormone. Treatment was given during a 12-week period throughout the peak phase of lactation. The rations of all animals were of grain and good quality pasture to appetite.

Growth hormone treatment resulted in a significant increase in daily milk yield during the first 6 weeks. During the remaining 6 weeks the yields of all 3 groups tended to decline in a parallel manner. The yields of the animals receiving growth hormone fell to the level of the controls once treatment ceased. There was a slight increase in the daily milk yields of the animals receiving thyrotropin but the yields fell below those of the controls when treatment stopped. The butterfat content of the milk of the animals treated with thyrotropin increased slightly. Milk protein, lactose and solids-not-fat were not affected by treatment. Treatment with growth hormone and thyrotropic hormone significantly increased heart rate. Growth rate was depressed by thyrotropic hormone therapy. Blood sugar and total acetone bodies rose in both treated groups. There was no alteration in the level of blood N.P.N. Treated animals showed increased efficiency of feed utilisation.

In the second experiment the response to growth hormone during the declining phase of lactation

was measured on 4 sets of identical twins. The amount used was the same as in the first experiment. The animals were fed on pasture alone. Treated animals again showed a significant increase in milk yield accompanied by an increase in efficiency of milk production.

The physiological mechanisms involved in these responses are discussed.—J. N. Aitken.

5814

HANCOCK, J., BRUMBY, P. and TURNER, C. W. The influence of L-thyroxin upon the growth and subsequent production of identical-twin dairy heifers. *N.Z. J. Sci. Technol.* [A], 1955, 36, 571-585. [Ruakura Animal Res. Stat., Dept. Agric., Hamilton.]

Six pairs of identical twin dairy heifers were used. After mating one member of each set was given subcutaneous injections of L-thyroxine at daily rates per 100 lb. liveweight of 0.5 mg. for the first 3 weeks, 0.45 mg. for the next month and 0.4 mg. for the remainder of a 6-month period. Heart rate, bodyweight and body measurements were recorded. Grazing habits were recorded during the second month of treatment and after parturition milk yield was recorded.

Rate of weight gain was reduced, particularly during the last 3 months of treatment. Recovery was rapid after treatment stopped and consequently at calving there was no significant within-set difference. Any difference remaining tended to disappear by the end of lactation.

Chest girths increased at a smaller rate in treated than in control animals. There was a sudden fall in middle girth measurements when injections were begun. Differences in this measurement tended to disappear as parturition approached. The treated animals showed also an increase in rate of gain in height at withers, in width of hip bones and in hip to pin bone measurement. The differences become smaller during the pre-calving and lactation periods. During treatment heart rate increased significantly. Although treated animals spent less time in grazing it was estimated that their feed intake was greater than that of control animals. Milk and butterfat production was reduced, especially in the first 3 months of lactation.—J. N. Aitken.

5815

VAN KOETSVELD, E. E. Welke betekenis moeten wij toekennen aan zwavel voor plant en dier, in het bijzonder voor het rund? [What significance should we attach to sulphur for plants and animals, particularly for cattle?] *Tijdschr. Diergeneesk.*, 1955, 80, 525-550. [Inst. Moderne Veevoeding "De Schothorst", Hoogland.] English, French and German summaries.

Literature is reviewed. Original data are presented for dry matter, crude protein, true protein, total S as SO_4 and sulphate SO_4 and Cu in grass samples, from May to September, from experimental plots. Values for S, organic and inorganic, were approximately the same in spring and autumn, with a minimum in July. Cu and protein varied together. As protein fell, inorganic S sometimes rose. Analyses of hay showed that the more rapid the drying the less was the loss of sulphur amino-acids and the less the sulphate S. S is less readily leached from grass than is Cl.

Analyses of soil samples showed that sand contained only traces of S. The substitution of Thomas meal for superphosphate, as is common at present, will increase the danger of deficiency. With peat-clay soils the results of t'Hart were supported, but those of Grashuis, who found more S in the top-soil than in the next layer, were not confirmed. There was sometimes no difference between the top 5 cm. and the layer 5 to 20 cm., but the top had much more S when there was a difference.

The sulphate of drinking water varies widely in the Netherlands, between 17 and 114 mg. SO_4 per litre in 10 samples. On 4 farms where the water contained 81, 93, 94 and 114 mg. SO_4 per litre there was diarrhoea or Cu deficiency or both; the condition of the cattle in general was poor.

If a cow eats 15 kg. dry matter of grass with a sulphate content of about 0.5 per cent., the intake will be about 75 g. SO_4 . If she drinks 10 litres water, she will get at least 100 mg. SO_4 and may get much more, up to 2 g. Total intake may vary between 75 and 150 g. An excess of the order of 75 g., with excess of protein in the spring, is thought possibly to cause formation of H_2S and histamine. In the autumn the excess of inorganic SO_4 may be responsible for the diarrhoea and interference with absorption of trace elements, or may form H_2S which may enter into insoluble compounds with Cu.

Data are presented for the SO_4 content of cow's milk, from cows fed in the same way in the same herd: 4 morning and 4 evening samples (same day), 4 samples on 2 consecutive days and 2 samples of pooled milk. Per cent., SO_4 varied from 7.0 to 14.6 mg.; total output in milk from 780 to 2774 mg. daily.

SO_4 in blood of 9 normal cows, 5 normal calves 2 months old, and 8 cows with grass tetany showed, in that order, the following ranges in mg. per cent., 12.0 to 13.9, except for a preparturient cow, 16.6, and one in heat, 16.9; 9.1 to 14.2; 15.2 to 19.0. Mg in the blood of the cows with tetany had a range from 0.3 to 0.5 and later, when the Mg range was 0.8 to 1.6, the SO_4 range was 14.1 to 18.6. In this investigation no value higher than 21 mg. was found, and it is suggested that SO_4 is a threshold substance.—I. Leitch.

MILLER, W. J. and ALLEN, N. N. The effect of sodium acetate feeding on milk and fat yield, blood sugar, and blood ketones of dairy cows. *J. Dairy Sci.*, 1955, 38, 310-312. [Dept. Dairy Husb., Univ. Wisconsin, Madison.]

Milk yield, butterfat yield and percentage, and blood sugar and ketone values of 18 dairy cows of 4 breeds were estimated during a period of 6 days. Half of the cows were given a supplement of 1 lb. Na acetate daily in addition to the normal ration. Before the test period there was a preliminary period of 4 days. No significant difference between control animals and those getting Na acetate was observed in any of the characteristics investigated.

KRÜGER, L. and MÜLLER, W. Untersuchungen zur Frage Fresspsyche (Fresslust), Futterabnahme, Futterverwertung und Milchleistung beim Rind. [Appetite, feed intake, feed utilisation and milk yield in cattle.] *Ztschr. Tierzücht. Züchtungsbiol.*, 1955, 64, 313-332. [Inst. Tierzucht, Justus Liebig Hochschule, Giessen.]

For a general account of the work, part of which is here reported in detail, see Abst. 2898, Vol. 25. Appetite, measured as g. dry matter eaten per min., increased with the amount of feed. The extremes were 42, with a feed intake of 1.1 to 3.0 kg. dry matter, to 198, with a feed intake of 5.1 to 7.0 kg. In the 4 weeks commencing 10 days after calving, the highest total daily feed intake was roughly 24 and the least 16 kg. dry matter and these as percentages of feed offered [*Futterabnahme*] were 98 and 89. In all cows tested, appetite increased with milk yield over the interval studied and milk yield was related also to daily feed intake at the peak of lactation. The 300-day yields also were

N.A. and R., October 1955

related to appetite and to total intake when feed was offered to appetite.—I. Leitch.

5819

VOISIN, A. Verhalten und Sättigung der Kuh auf der Weide und im Stall. [Behaviour and satiety of cattle on pasture and in the stall.] Reprinted from Lecture Reports, 8th Meeting Landwirtsch. Fak., Bonn-Poppelsdorf, 13-14 September 1954, pp. 42. [Gruchet-Sur-Arques, Dieppe.] French summary.

Kellner's theory was that the quantity of food which a cow can eat can be measured in terms of dry matter, but different authors have estimated it, for a cow of 500 kg. liveweight, as from 10 to 17 kg. dry matter daily. According to German tables, the quantity varies with production, from as little as 8 kg. for dry cows to as much as 20 kg. for a cow giving 30 kg. milk daily. The theory of Lehmann was that a cow of 500 kg. liveweight can eat about 4.3 kg. of indigestible "ballast" before being satiated, and that the quantity remains the same whatever her milk yield. The role of appetite has scarcely been considered.

Observations on the cow at pasture suggest that on poor pasture eating may stop before a sufficient quantity of digestible matter has been taken, the cow appearing to be fatigued with the effort of eating. It is concluded that when feed is succulent enough to need little mastication the amount consumed is limited by the "ballast" content, and with feeds high in fibre the work of chewing limits the amount consumed.

A new interpretation is placed on Kellner's "Wertigkeitskoeffizient". The work of mastication of a feed is involved in it. The maximum daily energy expenditure of a cow of 500 to 600 kg. liveweight in mastication is estimated to be about 1680 Cal.

From a practical viewpoint the limitation of fatigue is best accomplished at pasture by rotational grazing, so that the cow is confined to a small area of grass 12 to 15 cm. high, which provides the best nutritive value (cf. Abst. 5771, Vol. 25). In the stall it is best to use early-cut hays which are low in ballast value and to chop coarse fodders so that they are more easily eaten.

MAHADEVAN, V. The role of "bulk" or "roughage" in the ration of dairy cows and buffaloes. *Indian Vet. J.*, 1954, 30, 359-363. [Dept. Animal Nutrit., Madras Vet. Coll.]

5821

WARD, G. M., HUFFMAN, C. F. and DUNCAN, C. W. Urea as a protein extender for lactating cows. *J. Dairy Sci.*, 1955, 38, 298-302. [Dept. Dairy Chem., Michigan State Coll., East Lansing.]

Vol. 25, No. 4

The value for milk production of a low-protein roughage ration supplemented with either maize and urea or soya bean oilmeal was tested in an experiment of Latin square design with 10 cows. The effectiveness of the N supplement when the concentrates were mixed with the roughage or placed on top of the roughage was also determined. There was no significant difference in production of fat-corrected milk. Observations of the eating habits of the cows showed that when the concentrates were mixed with the roughage the cows promptly separated them and consumed them before eating the roughage. No benefit resulted from this method of feeding.—J. N. Aitken.

5822

ROLLINSON, D. H. L., HARKER, K. W. and TAYLOR, J. I. Studies on the habits of Zebu cattle. 3. Water consumption of Zebu cattle. *J. Agric. Sci.*, 1955, 46, 123-129. [Animal Health Res. Centre, Entebbe, Uganda.]

For previous parts see Absts. 5400, Vol. 24; 4335, Vol. 25.

The drinking habits of the cattle in the previously reported investigations were recorded. Water was taken mostly within 8 hr. of the day falling between 7 a.m. and 7 p.m., and very little was taken during darkness. The daily consumption of 2 of the cattle kept in stalls for 36 days was 4.19 and 5.68 kg., but the average of the 10 grazing animals was 9.04 kg. Sometimes drinking was confined to periods of less than 6 hr., sometimes spread over 12 hr., but intake during the 24 hr. was about the same in each case. When drinking was confined to a few hours there was a significant negative correlation of -0.715 with the number of times grazing occurred: when drinking was spread over 7 to 12 hr., the correlation was -0.555 , which was also significant. In this experiment there did not appear to be any relation between the liveweight of the animals and their water consumption.—T. D. Bell.

5823

BERGE, S. Kroppsvekt og mjølkeavdræt. [Body-weight and milk yield.] *Tidsskr. norske Landbruk*, 1955, 62, 59-70. English summary.

Estimates of the relation of milk yield to body-weight in dairy cows by Brody (Abst. 3813, Vol. 15), Axelsson (SRB, 1940, No. 4, p. 5), Lauprecht and Döring (Abst. 6039, Vol. 20) and Hansen-Larsen (SRB, 1953, 25, 100) are discussed. The relation is of the form $M = kW^a$ and the power and constant depend on breed, yield, age of cow and, except within one breed, fat content of milk. For example, the constant varied in the German data for Holstein cows from 54.5 in the district of lowest yield to 62.5 in that with the highest

yield. Fat percentage in the Danish data, where the effect of age was eliminated, was not related to weight of cow. The power of weight was 0.5, but this may be too small for cows in general, since the data refer to elite herds. In the German data, a power of $2/3$ is probably too high because the cows were of all ages.

Norwegian milk records, grouped by area and according to weight of cows estimated from measurements, give the equation $M = 32W^{0.75}$ for Norwegian cows in general. Those with the highest milk fat had a constant about 59. The maintenance feed requirement of large cows is relatively less than that of small cows and the requirement per kg. milk is independent of size. The cost of work or of housing does not differ greatly with size. Where pastures are poor or difficult of grazing, the small cow has the advantage as more agile. On the other hand, Sisson, "Anatomy of the Domestic Mammals", 3rd ed., 1940, Philadelphia) says that capacity of the gastro-intestinal tract is related linearly to body-weight. This being so, the big cow is at an advantage in relation to feed capacity.

The quickest way to increase milk production is to select cows for size, so long as it is not forgotten that, within herds, size and milk yield may be inversely related.—I. Leitch.

5824

FLUX, D. S. and PATCHELL, M. R. A comparison of the milk production of cows on different systems of break feeding. *N.Z. J. Sci. Technol.* [4], 1955, 36, 557-559. [Dairy Res. Inst., Palmerston North.]

Two groups of 6 cows each were used in a double reversal trial covering 3 periods each of 3 weeks' duration. There was no significant difference in the milk production of cows given 2 fresh breaks of grass daily in comparison with those given only one.—J. N. Aitken.

5825

BURT, A. W. A. Some effects of season of the year and herd management upon the Dairy Short-horn cow. 1. The effects of seasonal changes in climate, feeding and management upon the milk yields of four herds. *J. Agric. Sci.*, 1955, 45, 389-400. [Dept. Agric., Univ. Coll. Wales, Aberystwyth.]

Milk records and records of farm and herd management collected over a 2-year period were used. Differences between herds in mean lactation yield were attributable to differences in weather conditions and management. A weekly yield index was calculated for each herd after making allowances for mean stage of lactation and changes in potential productivity. Variations in the yield index were used to measure the effects of changes

in climate, feeding and management. The results varied from herd to herd but were fairly consistent within herds from year to year. In 3 of the herds which were housed during the winter, the start of the winter feeding was associated with an increase in the yield index. Changes in the winter roughage ration resulted in a decline in the yield index. In the fourth herd, which was out-wintered, there was a serious decline in the yield index between September and December. Subsequent recovery was associated with seasonal weather changes. It was concluded that most of the changes observed were related to roughage feeding and management.

J. N. Aitken.

5826

PRESTEGG, K. Lønner det seg å bruke kraftfôr i mjølkeproduksjonen i dag? [Does it pay to use concentrates in milk production to-day?] *Buskap og Avdrått*, 1953, No. 3, pp. 7.

It pays to use concentrates up to the feeding standards in common use, provided that they are rationed according to milk yield and provided that no more cows are kept than are required to eat the home-produced roughage. To use more concentrates simply to increase the size of the herd is uneconomic. Improved roughage with controlled concentrates pays best.—I. Leitch.

5827

TURNER, C. Self-fed silage. The effect on management and policy. *Agriculture, J. Minist. Agric. Engl.*, 1955, 62, 118-122. [Nat. Agric. Advisory Serv., Bucks.]

The system of self-feeding silage to dairy cows has already been described (Abst. 2507, Vol. 24). It necessitated some reorganisation of the farm, and this is described. No increase in labour has been necessary and 300 tons of silage have been produced at a cost of £5 per ton. For the past year no concentrates have been used, while milk yield has been maintained at a high level. In future it is proposed to give 2 to 3 lb. cereals per cow daily, with added minerals, since there have been signs of magnesium deficiency recently.

T. D. Bell.

5828

WENIGER, J. H., FUNK, K. and HARTWIG, W. Der Futterwert der Kakaoschalen und ihre Wirkung auf die Milchproduktion. [Feed value of cocoa shell and its effect on milk production.] *Arch. Tierernährung*, 1955, 4, 337-348. [Inst. Tierzucht, Univ. Halle.]

The roasted and crushed cocoa shell was divided mechanically into coarse and fine fractions, the former, A, containing only the outer shell, and the latter, B, some of the kernel and thus more protein and fat and less fibre. In digestibility trials with 3 wethers the digestibility of the organic matter was 42.2 and 47.3 per cent. for types A and B, the

N.A. and R. October 1955

starch values in 90 per cent. dry matter were 36.6 and 42.5 kg. and the digestible crude protein 4.9 and 5.5 per cent., comparable to meadow hay or dried beet slices.

In tests with dairy cows from 0.5 to 2 kg. daily was given without ill effect and the fat content of the milk was increased, though the milk yield fell slightly. This is ascribed to theobromine. Cocoa shells can safely be given as bulk food to cows, in quantities up to 2 or 3 kg. daily.—D. Duncan.

SPRAGUE, V. G., WILLIAMS, P. S., KNOTT, C. B., KESLER, E. M. and HASKINS, A. L. **Seasonal distribution and production of forage and milk from orchard grass-ladino and blue grass pastures.** *Pennsylvania Agric. Exp. Stat. Bull.* No. 592, December 1954, pp. 13.

Over 5 years paddocks of a pasture sown with cocksfoot and ladino clover in the first year were subjected to 5 different grazing treatments: (1) early spring grazing, then rotational grazing; (2) deferred spring grazing, then rotational grazing; (3) early spring grazing, cutting of the first aftermath for silage, then rotational grazing; (4) spring growth cut for silage, then rotational grazing, and (5) continual grazing from spring to autumn. A pasture sown to Poa and white clover was grazed rotationally throughout the season. Dry matter of forage, number of cow-grazing days, and milk produced per acre, excluding silage, were estimated. The cattle were dairy cows about 4 years old, receiving in addition to the grazing 2.3 lb. concentrates.

There was a close correlation between dry matter of forage, excluding silage, cow-grazing days and milk produced per acre from grazing. Paddock 2 was the most productive, followed by 5, and the Poa pasture was equal to two-thirds of these. On different paddocks production was maximum at different times: usually at least half of the forage was produced over a short spell of one season. A combination of the types of management should be used in practice. The proportion of ladino clover was best maintained

in paddock 1, and protein as a percentage of the total dry matter was highest where there was most ladino clover. It was also higher in all pastures in spring and autumn than in summer. In the last 2 years of the trial all the pastures were declining in productivity.—T. D. Bell.

REPRODUCTION

5831

DURRELL, W. B. **Anoestrus in heifers associated with plane of nutrition.** *Canad. J. Comp. Med.*, 1955, 19, 144-152. [Dept. Animal Pathol., Macdonald Coll., Que.]

This investigation was suggested by observation that anoestrus in heifers occurred annually from January to May on certain farms in Western Quebec. The condition was associated with a low plane of nutrition. A study was made on 36 heifers on 12 farms. Data on health and disease were noted for each animal and for 21 selected controls which were showing oestrus regularly. The condition was corrected in 61 per cent. of the animals when a balanced grain mixture was given at the rate of 5 lb. daily. Non-recovery in some cases was attributed to inadequate lighting and the very poor condition of the animals at the start of the trial. It is suggested that in this disorder improvement in nutritional status should be considered before hormone therapy is attempted.

SHEEP

5832

NATIONAL RESEARCH COUNCIL, U.S.A., COMMITTEE ON ANIMAL NUTRITION. **Recommended nutrient allowances for domestic animals. 5. Recommended nutrient allowances for sheep.** Revised August 1949, pp. 24.

The report collates all available reliable experimental work on the nutrition and feeding of sheep and presents it in a form suitable for practical use.

Vol. 25, No. 4

In calculating allowances, maintenance, growth, lactation, wool growth, feed quality and climatic conditions have been taken into consideration. The recommended daily nutrient allowances per animal of total feed, total digestible protein, total digestible nutrients, calcium, phosphorus, salt and carotene are given in tabular form for ewes in different stages of pregnancy and lactation, and growing and fattening lambs and rams. Vitamins,

effects and signs of nutritional deficiencies, toxicity of excess minerals and other nutritional disturbances are discussed. Further tables give the composition of feeds and provide examples of dry-lot rations for pregnant and lactating ewes and for fattening lambs.—J. C. Gill.

5833

OWEN, J. B. **Milk production in sheep.** *Agriculture, J. Minist. Agric. Engl.*, 1955, **62**, 110-114. [Univ. Coll. N. Wales, Bangor.]

The milk yield was estimated of lowland ewes and of hill ewes on the hill and on lowland pastures. The difficulties of estimating milk yield under natural conditions are discussed; the method used was to allow the ewe and lamb to graze together during the recording period, the ewe having a light sacking udder cover which prevented the lamb sucking. At suckling time the cover could easily be manipulated. Yield was estimated for one 24-hr. period each week. Weights of ewes at service and parturition and weights of lambs at 10 weeks were recorded. Width of udder at parturition was measured. The total yield of the lowland ewes in 10 weeks was 157.9 lb., a high daily level being maintained somewhat longer than in the hill ewes. The yield of ewes on the hill was 109.3 lb., and of hill ewes on lowland pasture 171.6 lb., indicating the importance of feeding and environment for milk production. The weights of lambs at 10 weeks were: lowland 44.8 lb., hill 36.2 lb. and hill on lowland 53.4 lb. In the early stages most of the variation in the weights of lambs was directly related to the milk yield of the dams. The growth rate of the lamb in the first 4 weeks was considered a good indication of the milking capacity of the ewe. A close relation was found also between the birthweight of the lamb and the milk yield of the mother, and in hill sheep between the weight at service and the milk yield. From this the importance of adequate nutrition and good early growth of ewes kept for breeding is apparent. The width of the udder was closely related to milk yield and to the growth of the lamb during the first 4 weeks. Milk yield was well maintained in subsequent years, and was strongly heritable in hill ewes. Selection for milk yield could be conveniently based on weight of the ewe and growth rate of the lamb to 4 weeks. There was no relation between fleece weight and milk yield.—T. D. Bell.

NOLAN, J. C. and HILSTON, N. W. **Utilization of non-protein nitrogen by pregnant ewes (1952).** *Wyoming Agric. Exp. Stat. Mimeo Circular* No. 32, June 1953, pp. 14.

Five groups of 20 pregnant yearling ewes were used in a trial to compare supplements of soya

bean meal, urea or combinations of the two. The control group 1 was given a ration of hay, maize and beet molasses, supplying adequate total digestible nutrients but less than the minimum protein requirement. The experimental groups got the same with urea or soya bean meal or both to give a balanced ration on the basis of crude protein. Group 2 had urea only; group 3 had one-quarter urea and three-quarters soya bean meal; group 4 half urea and half soya bean meal and group 5 soya bean meal only. The trial lasted 113 days, and the ewes were shorn before lambing and the fleeces were weighed.

Satisfactory gains in weight were made by all groups, but the final weight of group 5 was significantly greater than that of groups 1 to 4, and that of groups 2 to 5 significantly greater than that of group 1. Lambs of ewes from groups 2 and 5 were significantly heavier than those of groups 1, 3 and 4, and there was more lambing trouble in groups 1, 2 and 4. Lambs of groups 1 and 2 were less vigorous than the others. The extra energy supplied by the soya bean meal may have influenced the results.—T. D. Bell.

5835

MASON, R. W., STRATTON, P. O. and HILSTON, N. W. **Utilization of non-protein nitrogen by pregnant ewes.** *Wyoming Agric. Exp. Stat. Mimeo Circular* No. 35, December 1953, pp. 13.

The trial was similar to that reported in the preceding Abst. but, in this case, to eliminate the possible effects of the extra energy supplied by the soya bean meal the rations for the 5 groups were made equal in energy by varying the amount of maize. Group 1 received only urea as a supplement; group 2 had three-quarters of the crude protein supplied by urea and one-quarter by soya bean meal; group 3 had one-half urea and one-half soya bean meal; group 4 had only soya bean meal and group 5 was the low-protein control, getting only the basal ration. The trial lasted 126 days. The ewes had been served to lamb during the last month of the trial, and were shorn 6 weeks before the end.

Final weights of group 4 were significantly greater than those of group 1, which were the lightest. However, there were more non-lactating ewes in group 4 than in group 1; group 5 also had a high percentage of non-lactating ewes, which might explain the high final weights of that group as a whole, in spite of the poor ration. If only the lactating ewes were considered, those in groups 3 and 4 gained best. The fleece weights of group 1 were significantly greater than those of the other groups. Birthweights of lambs of the supplemented groups were greater than those of group 5, and they were more vigorous. The lambs from

N.A. and B., October 1955

group 5 grew less well than those of the other groups.—T. D. Bell.

IVANENKO, V. I. Vliyanie sochnykh kormov i belkogo pitaniya karakul'skikh suyagnykh matok na ikh produktivnost'. [The effect on production of giving succulent feeds and proteins to pregnant Karakul ewes.] *Karakul. Zverovodstvo*, 1954, 7, No. 6, 18-25. [Ukraine Sci. Res. Inst. Animal Management.]

Several series of experiments are discussed, the first dealing with the effect of increased protein content of the ration, 50 to 60 per cent. above the existing standards, and the second with the effect of different succulent fodders at different stages of pregnancy.

In the first series one group received 78.5 g. digestible protein (total feed units 1.03), another group 127 g. (total feed units 1.03) and the third group 130.5 g. (total feed units 1.10). The greatest increase in liveweight was in the third group. Increasing the protein content of the ration also produced higher yields of milk and wool and better lambs. In the series comparing different succulent fodders, silage increased the milk yield, particularly when it was given during the second stage of pregnancy. At this stage, however, only about 0.5 kg. of succulent fodders should be given per ewe daily, since higher amounts impaired the quality of the wool.—H. Scherbatoff.

TANEJA, G. C. The effect of drought and type of birth on body weights of Merino sheep measured at different ages. *J. Austral. Inst. Agric. Sci.*, 1955, 21, 26-29. [New South Wales Univ. Technol.]

Results from 284 spring-born and 269 autumn-born Merino ewe lambs indicated that at 5, 11 and 17 months of age those born early in spring were heavier than those born late, but no difference in weight was found between early and late autumn lambs of the same ages. The difference in spring may have been due to season and drought feeding. Bodyweight at one age was closely related to bodyweight at any other age. Between 5 and 11 months, 5 and 17 months and 11 and 17 months correlations were +0.630, +0.644 and +0.676 with a multiple correlation between the three of +0.732. A single lamb was significantly heavier at the 5 per cent. level than a twin at 5 months but not significantly heavier at 11 and 17 months.

TANEJA, G. C. The relative importance of heredity and environment in body weight increments at different ages in Australian Merino sheep. *Austral. J. Agric. Res.*, 1955, 6, 343-349. [Sch.

Vol. 25, No. 4

Wool Technol., N.S.W. Univ. Technol., Sydney.]

Rates of growth between 5 and 11 and between 11 and 17 months of age of 284 lambs born in spring and 269 born in autumn were studied. Environment had more effect than heredity on growth rate. The effect of environment was greater in the earlier period, and no relation was found between the environmental effects in the 2 periods. Genetic effects in the 2 periods also showed no correlation, which suggested that different sets of genes were operating in the 2 periods.—T. D. Bell.

WUSSOW, W. and KÖNIG, K. H. Der Einfluss unterschiedlicher Jugendernährung auf Entwicklung und Schlachtergebnis von Lämmern. [Effect of different diets in youth on development and slaughter results of lambs.] *Arch. Tierernährung*, 1954, 4, 1-24. [Inst. Tierzucht, Martin Luther Univ., Halle, Wittenberg.]

Ten wether and 10 ewe lambs of the Merino mutton breed were divided into 2 similar groups at a mean age of 117 days and stall-fed for 15 weeks. Two of each sex in each group were then killed and the rest were put out to pasture with the flock until they were brought in for fattening and slaughtered at 13 months of age. The 2 experimental diets, high and low in bulk, provided on the average during the 15 weeks, in g. per head daily, lucerne hay 615 and 149, oats 100 and 273, dried beet pulp 285 and 213, linseed meal 25 and 152, pea meal 25 and 152 and green fodder 1394 and 907. The composition of these rations, also in g. per head daily, was digestible crude protein 141 and 136, starch value 606 and 622, dry matter 1232 and 1022, crude fibre 312 and 192.

To begin with the high-fibre group grew more quickly, but by the 14th week the low-fibre group had almost caught up, because their appetites improved. Both groups, but especially the low-fibre group, had a check for about 2 weeks when they were shorn. When the survivors of each group went out to pasture they lost on the average 3.57 and 2.57 kg. liveweight in the first week. The low-fibre group then went ahead, but by the end of the pasture period the two groups were equal.

There was no great difference in body measurements between the 2 groups. The wool clips both in the early period and at the end of the pasture

period were higher in the high-fibre group, though staple length was similar. Carcase measurements in the animals killed early were similar, but the low-fibre animals contained more bone and the meat had a higher protein content. The sheep killed at 13 months of age showed more difference in favour of the high-fibre group, which contained a higher proportion of meat and also more fat. They tended to have greater length and volume in the digestive tract, but this was not significantly related to body size.

It is concluded that the high fibre intake in early life was advantageous.—D. Duncan.

5841

GUYER, P. Q. and DYER, A. J. **Study of factors affecting sheep production.** *Missouri Agric. Exp. Stat. Res. Bull.* No. 558, July 1954, pp. 79.

Thirty-two 2-year-old ewes on bluegrass pasture given a supplement of 2 lb. concentrates per head daily during the last 60 days of pregnancy were compared with an unsupplemented flock on the same pasture. The supplemented ewes made greater gains during pregnancy, had heavier fleeces, produced larger lambs at birth and gave more milk. Lambs from the supplemented ewes were heavier at 16 weeks and were marketed earlier and at higher prices. A supplement to ewes on fescue-ladino pastures resulted only in heavier fleeces and heavier twin lambs at birth. Dystocia was not associated with size and type of sire or body conformation of ewe. Single lambs after a large ram were heavier at birth and made faster growth than those after a small ram. There was little difference with twins. Milk consumption, lambs per ewe, and birthweight were closely related to rate of growth of lambs. Milk yield was highest in the second week after lambing and total yield was greater with twins than with single lambs. There was little difference in the growth rate of ewe and wether lambs. An extensive review of the literature is included.

BUSH, L. F., WILLMAN, J. P. and MORRISON, F. B. **A study of the protein requirements of fattening feeder lambs.** *J. Animal Sci.*, 1955, 14, 465-469. [Cornell Univ., Ithaca, N.Y.]

In trials with 297 lambs, those fed on rations containing 11.8 per cent. total protein made higher average daily gains than did those on 10.0 and 11.0 per cent. protein. Feed efficiency was similar at all levels. Rate of gain and degree of finish were not significantly affected by the amount of alfalfa hay given with a full feed of maize silage, but lambs on maize silage alone showed greater feed efficiency than did those on a full feed of silage plus 0.75 or 0.50 lb. hay.—J. C. Gill.

5843

HÄRING, F., LEYDOLPH, W. and SCHOLZE, F. **Milchlämmermast auf unterschiedlicher Futtergrundlage. [Fattening milk lambs on different basal diets.]** *Arch. Tierernährung*, 1954, 4, 25-33. [Inst. Tierzucht Milchwirtsch., Univ. Göttingen.]

Two groups were used, each of 16 ewes, with 21 and 20 lambs; several breeds and crosses were included. Each ewe of group A received, in kg. daily, improved fodder beet 1.5, meadow hay 0.25, oat straw 0.5, beet leaf silage 1.5, Troblako [a preparation of dried beet leaves] 0.25; ewes with single lambs received protein feed 0.15 and meadow hay 0.25, those with twins 0.3 and 0.5. Those of group B received fodder beet 3.0, lucerne hay 0.25, oat straw 0.5 and Troblako 0.25, ewes with single lambs oats and beans 0.15 and lucerne hay 0.25 and those with twins 0.3 and 0.5. The two rations provided before lambing, in g. daily, digestible protein 74 and 105, starch equivalent 509 and 435; for ewes with single lambs protein 113 and 138, starch equivalent 673 and 634; for ewes with twins protein 152 and 190, starch equivalent 837 and 813. All lost some weight during the experiment. All lambs received at 2 weeks of age oats and lucerne hay; later those of group A got protein feed and Troblako, those of group B oats and beans.

Single lambs gained during the experiment 284 and 264 g. daily, twins 250 and 206 g. The single lambs, ate, for each kg. liveweight increase, digestible protein 270 and 259 g., starch equivalent 1247 and 1339 g. For twins the values were 287 and 283, 1305 and 1392.

The lambs were killed at about 35 kg. liveweight, means for group A 35.9 and for group B 34.0 kg. The carcase weights were 17.6 and 16.5 kg., or 51.8 and 51.4 per cent. The fat yields were 6.8 and 7.9 per cent. of the carcase weight.

BOTKIN, M. P. and PAULES, L. **Effect of aureomycin in various ratios of roughage to concentrate for feeder lambs.** *Wyoming Agric. Exp. Stat. Mimeo Circular* No. 44, April 1954, pp. 7.

Different ratios of roughage to concentrate, 1:1, 1.5:1 and 2:1, each with or without aureomycin supplied as Aurofac 2A, 6 lb. per ton feed, were compared for fattening lambs. About 50 lambs were self-fed and 16 hand-fed on each treatment. The roughage was alfalfa hay and the concentrate was two-thirds whole barley and one-third dried beet pulp. When similar ratios of roughage to concentrate were compared, aureomycin gave a slight but insignificant improvement in efficiency of feed conversion and dressing percentage, but was uneconomic because of the high cost of the antibiotic. Rate of liveweight increase, efficiency and

N.A. and R., October 1955

dressing percentage decreased as the proportion of roughage increased. Hand-fed lambs gained more slowly and were less efficient than self-fed but dressing percentage and price per lb. were higher. In the hand-fed lambs a correlation of + 0.80 was found between rate and efficiency of gain when initial weight was constant.—T. D. Bell.

5845

JORDAN, R. M. **Alfalfa hay, alfalfa silage and corn silage for fattening lambs.** *S. Dakota Agric. Exp. Stat. Circular* No. 106, April 1954, pp. 6.

Three trials were made to compare alfalfa hay, alfalfa silage and maize silage as roughages for fattening lambs. In each trial the lambs received the same concentrates and the group getting silage was also given a small quantity of alfalfa hay. In the first trial rate of growth and efficiency were greater on the alfalfa hay, which was leafy and green in this trial. In the other trials the silages were superior to the brown, somewhat stemmy hay used. There was little to choose between the 2 silages in any trial. Dressing percentage and carcass grade were not influenced by the rations given.—T. D. Bell.

5846

FAULKNER, E. K. and PAULES, L. **Saffmeal for fattening lambs (second year's trials).** *Wyoming Agric. Exp. Stat. Memo Circular* No. 12, March 1952, pp. 7.

Five groups of lambs of initial liveweight 75 lb. were used to compare saffmeal (safflower meal) of 18 and 28 per cent. protein content with soya bean oilmeal of 41 per cent. protein content, given on an equivalent protein basis, as protein supplements, and to compare self-feeding with hand-feeding. The trial lasted for 112 days, when the lambs were killed at about 110 lb. liveweight and graded. The concentrates were made up of whole barley, and for group 1, 28 per cent. protein saffmeal, group 2, 18 per cent. protein saffmeal, group 3 soya bean oilmeal, group 4, 28 per cent. saffmeal and group 5, 18 per cent. saffmeal. Groups 1 and 2 were self-fed and the others were hand-fed. Costs of fattening based on local current prices were estimated.

The 28 per cent. saffmeal gave cheaper and faster gains than the 18 per cent. saffmeal fed in the same way. Self-feeding gave cheaper and faster gains than hand-feeding and also gave better carcass grade and dressing percentage. Group 1 was comparable to group 3 but cost of gain was slightly higher, though this was offset by higher carcass grade and dressing percentage. Weight increase of group 2 was equal to that of group 4, but efficiency of feed conversion was not so good and cost of liveweight increase was consequently higher.—T. D. Bell.

Vol. 25, No. 4

5847

MEYER, J. H., WEIR, W. C., ITTNER, N. R. and SMITH, J. D. **The influence of high sodium chloride intakes by fattening sheep and cattle.** *J. Animal Sci.*, 1955, **14**, 412-418. [Dept. Animal Husb., Univ. California, Davis.]

Growing and fattening sheep given rations with 0.66, 4.8, 9.4 and 12.8 per cent. of sodium chloride made similar daily gains and were equally efficient in feed utilisation. High sodium chloride intakes did not affect the digestibility of the ration, but there was some indication that carcass grade was reduced. Daily gain, feed efficiency and dressing percentage were not affected in fattening steers given 9.33 per cent. sodium chloride, but there was some decrease in carcass grade.—J. C. Gill.

5848

BUOY, L. L., GARRIGUS, U. S., FORBES, R. M., NORTON, H. W. and MOORE, W. W. **Toxicity of some arsenicals fed to growing-fattening lambs.** *J. Animal Sci.*, 1955, **14**, 435-445. [Dept. Animal Sci., Univ. Illinois, Urbana.]

Arsenic, as 3-nitro-4-hydroxyphenylarsonic acid, arsanilic acid, and potassium arsenite, was given at levels of 0.05, 0.1, 0.2 and 0.4 per cent. in a hay, maize and soya bean meal ration given to 12 individually penned lambs to appetite. The same amounts, with the omission of the 0.05 per cent. level, were given to 9 mature ewes in a second trial. There was no difference in growth of lambs due to the level or to the compound of arsenic. The rations containing 3-nitro-4-hydroxyphenylarsonic acid were eaten best, and this compound appeared less toxic than the others. Lambs getting 0.2 and 0.4 per cent. arsanilic acid had convulsions and the ewe on the 0.4 per cent. level died. Liver, kidney and muscle arsenic contents rose when arsenicals were given and pathological changes indicated severe haemolysis, not necessarily accompanied by outward signs of toxicity. J. C. Gill.

KOCH, W. and HEIM, E. **Der Einfluss der östrogenen Hormone auf die Schafmast und die Qualität des Schaffleisches.** [Effect of oestrogens on fattening of sheep and the quality of mutton.] *Züchtungskunde*, 1955, **28**, 343-355. [Inst. Tierzucht, Univ. Munich.]

Literature is reviewed. In the first experiment, 10 non-pregnant ewes, average weight 63.5 kg., were given 200 mg. Foragynol (Di-*p*-acetoxyphenylhexadiene) by injection in the neck; 8 similar ewes served as controls: 15 lambs, average weight 32.2 kg., were given 100 mg. of the synthetic oestrogen and 12, average weight 31.3 kg., were controls. After 28 days, the average weight of the treated ewes was 69.0, of the controls 71.0

kg. The treated lambs weighed on the average 41.4 kg. and the controls 38.0. The treated ewes, but not the lambs, lost weight for the first 6 days. There was no effect on quality of meat.

In the second series 20 wethers, average weight 65.6 kg., were given 200 mg. Foragynol; 5 were given both oestrogen and 1 ml. A.T. 10 to counteract the effect on Ca metabolism and 15, average weight 67.2 kg., were controls. At the end of the 43 days the average weights in the above order were 70.4, 73.0 and 75.5 kg. Again there was no effect on quality.

In the third experiment, 39 ram lambs, average weight 23.7 kg., were given 100 mg. oestrogen and 40, average weight 23.3 kg., were controls. At the end of 59 days the average weights were 35.5 and 33.4 kg. and quality was not affected. Five of the treated lambs showed inflammatory changes in the testes and these lost weight.

Quality was measured in terms of water content and intramuscular fat.—I. Leitch.

5850

MAQSOOD, M. Effects of the thyroid gland on fleece growth in sheep. *Brit. Vet. J.*, 1955, 111, 163-169. [Animal Res. Stat., Univ. Cambridge.]

Suffolk rams 4½ months old were given thyroxine or thiouracil in their diets for 11 months. Similar

animals were kept as untreated controls. Thyroxine increased and thiouracil decreased fleece weight and fibre length significantly. Diameter of fibres was not affected.—T. D. Bell.

5851

SELLERS, K. C. and LEECH, F. B. Survey of losses associated with pregnancy and parturition in Yorkshire sheep. *J. Agric. Sci.*, 1955, 46, 90-96. [Vet. Invest. Centre, Minist. Agric. Fish., Leeds.]

The survey included 4 per cent. of the flocks and 6.3 per cent. of the breeding ewes of Yorkshire during the exceptionally favourable lambing season of 1953 after severe weather at mating time. Lambing was successful in 89.68 per cent. of the breeding ewes and barrenness accounted for 3.66 per cent. of the 10.32 per cent. which did not breed successfully. In the Holderness area there were few abortions but rates of stillbirths and deaths of ewes during pregnancy and parturition were high. In the Wolds, where pregnant ewes are folded on arable crops and where *Vibrio foetus* infection is known to be present, the incidence of abortion was twice that in other areas. Hay feeding appeared to reduce mortality in all regions. J. C. Gill.

BARBER, R. S., BRAUDE, R. and MITCHELL, K. G. Studies on milk production of Large White pigs. *J. Agric. Sci.*, 1955, 46, 97-118. [Nat. Inst. Res. Dairying, Univ. Reading.]

Two gilts and 3 sows with litters were studied to ascertain the frequency of suckling. The litters, of ages ranging from 6 to 51 days, were continuously watched for 24 hr. The interval between sucklings was, on the average, about 1 hr., slightly less in the younger, slightly more in the older litters. The shortest interval was 25 and the longest 96 min., but most were between 50 and 70 min. During the 12-hr. period from 8 p.m. to 8 a.m. sucklings were slightly fewer than during the day.

In an experiment with 2 gilts suckling litters of 6 and 5, weight changes were recorded until weaning at 56 days. The litters were allowed to suck normally except for certain 48-hr. periods, spaced throughout the lactation, when suckling was controlled and piglets were allowed to suck only every 2½ or 3 hr.; finally there was one 24-hr. period when they sucked every hour. During these controlled periods piglets were weighed before and after suckling to measure the milk yields of the dams. When suckling was allowed

only at the longer intervals they lost weight during the controlled periods and for 24 hr. afterwards. Milk production over the 48-hr. was less than in the 24-hr. period when suckling was allowed every hour, although this latter period was nearer the end of lactation and yield could be expected to have declined. During each controlled period of 48 hr. yield was less in the second 24 hr. than in the first.

Milk yield of 3 gilts during 56 days' lactation was estimated from the milk consumed by the piglets, which were allowed to suck every hour during controlled periods of 24 hr. The estimated yield was 768 lb. Details of the behaviour during suckling, the choice of teats, the size of the piglets and the yield of the teats are described and discussed. Variations of yield of different teats and at different times were recorded. During the first 3 weeks, when they were getting only milk, the rate of growth of the piglets was directly related to their milk intake, but later, when creep feeding was available, the relation no longer held. On milk only, the efficiency of feed conversion was higher than during the last 5 weeks before weaning.

The chemical composition of the milk changed during the first 3 weeks, after which it remained

N.A. and R., October 1955

fairly constant. Fat increased from between 3.5 and 5.5 to between 8.5 and 10.0 per cent., total solids decreased from about 30 to about 20 per cent., and solids-not-fat from about 25 to about 11 per cent.—T. D. Bell.

5853

LASSITER, J. W., TERRILL, S. W., BECKER, D. E. and NORTON, H. W. Protein levels for pigs as studied by growth and self-selection. *J. Animal Sci.*, 1955, **14**, 482-491. [Illinois Agric. Exp. Stat.]

Pens of 5 pigs of average weight 31 lb. were self-fed on rations containing either 10, 12, 14 or 16 per cent. protein, there being 2 pens for each protein level. There were also 4 lots each of 10 pigs of average weight 29 lb. on four $\frac{1}{4}$ -acre paddocks of alfalfa pasture and self-fed on rations containing 8, 10, 12 or 14 per cent. protein. Protein selection tests were also made with pairs of pigs in dry lot and on pasture.

In dry lot, both before and after 100 lb. liveweight, rate and efficiency of gain tended to improve with each rise in protein level. Before 100 lb. growth rate on 10 per cent. protein was significantly lower than on 12, 14 and 16 per cent. protein, and growth rate on 12 per cent. protein was significantly lower than on 16 per cent. After 100 lb. growth rate on 10 per cent. protein was significantly lower than on the 12, 14 and 16 per cent. levels.

On pasture, both before and after 100 lb. liveweight, rate and efficiency of gain also tended to improve with each rise in protein level. Statistical analysis indicated that the optimum protein level was between 12 and 14 per cent.

Pigs under 100 lb. given maize with free choice of protein supplement selected diets with 13.7 or 15.3 per cent. protein when in dry lot and 10.8 per cent. protein when on pasture. After 100 lb. the pigs in dry lot selected diets with 10.9 or 12.7 per cent. protein and those on pasture 10.0 or 9.9 per cent. In dry lot the protein levels selected were lower when ground maize was given than with shelled maize.—I. A. M. Lucas.

HOHLS, H. W. Die Berechnung des maximalen täglichen Eiweißansatzvermögens von Schweinen aus in der Literatur veröffentlichten Daten und dessen Bedeutung bei der Durchführung von Fütterungsversuchen. [Computing the maximum daily capacity of pigs to lay down protein, from data published in the literature, and its importance in feeding experiments.] *Ztschr. Tierernährung Futtermittelk.*, 1955, **10**, 44-55. [Bundesforschungsanst. Kleintierzucht, Celle.]

Vol. 25, No. 4

In pigs the daily weight increase is proportional to the amount of the production ration only as long as the digestible protein content of the latter does not exceed the animal's ability to lay down tissue protein. When the limit is exceeded, the surplus protein is not laid down as meat. In comparing the values of different sources of protein it is important to restrict the quantities within the limit, otherwise differences are not truly shown. The maximum rates of protein deposition for several breeds of pig at weights between 50 and 150 kg. are shown in diagrams, and it is demonstrated that the amounts of protein used in feeding experiments are often too large. Several experiments are selected from the literature as evidence that too high a protein intake may distort the effects of antibiotic supplements.—D. Duncan.

5855

PAYNE, W. J. A., NAIDU, R. K. and SILLS, V. E. Pig feeding trials. The relative value and economy of animal, plant, and a mixture of animal and plant protein feeds in the ration of fattening porkers in Fiji. *Fiji Agric. J.*, 1954, **25**, 65-70.

A trial was made with 16 Tamworth \times Berkshire pigs fattened from 42 lb. liveweight, 6 weeks after weaning, to 120 lb. liveweight. Conditions prevented the trial from starting at weaning, so all the pigs were reared on plant protein until the trial could be begun. Then 4 rations were compared, designated high animal protein, group 1, low animal protein, group 2, high protein of mixed animal and plant origin, group 3 and high plant protein, group 4. Animal protein was supplied by meatmeal and dried buttermilk powder, and plant protein by cocoanut and groundnut meals. All animals had molasses and greenfeed, elephant grass, to appetite. The protein percentages of the rations were, for groups 1 to 4 respectively, 17.0 to 14.4, 12.4 to 9.9, 14.5 to 13.3, 14.4 to 12.4, the lower figures of each pair being the percentage protein given after 70 lb. liveweight was reached. Group 1 gained 1.26 lb. daily, required 2.95 lb. meal per lb. liveweight increase, took 62 days to reach slaughter weight of 120 lb., and had a dressing percentage of 80.3. For group 2 the corresponding figures were 1.05, 3.48, 72 and 77.2; for group 3, 1.34, 3.25, 54 and 81.3; and for group 4, 0.73, 3.55, 111 and 75.5. These results are discussed in relation to the findings of British workers in similar trials, and to the scarcity of animal protein supplements in Fiji.—T. D. Bell.

DAMMERS, J. De behoefte aan aminozuren voor groeiende varkens. [Amino-acid requirements of growing pigs.] *Tijdschr. Diergeneesk.*,

1955, 80, 361-365. [Rijkslandbouwproefstat., Hoorn.] English, French and German summaries.

In the first table all the known estimates of requirements of pigs for the amino-acids arginine, histidine, isoleucine, leucine, lysine, methionine, phenylalanine, threonine, tryptophan and valine as "per cent. of the ration", the weight of the pigs concerned and the percentage crude protein in the ration, are collected. Few of these estimates were made with synthetic diets and the amount of the amino-acid present may have been more than enough. In the second table are presented derived estimates of requirements suitable for diets with 13 to 17 per cent. crude protein, as is common practice in the Netherlands, in choosing which the minimum amounts in non-synthetic diets have been given most weight. They are in order of the list above, and as *l*-isomers except for methionine, phenylalanine and tryptophan which are *DL*, 0.25; 0.40; 0.65; 0.90; 1.00; 0.60 or 0.30 plus 0.30 cystine; 0.90 or 0.60 in the presence of tyrosine; 0.60; 0.20; 0.60 per cent. of the ration. These estimates are close to those for the rat (see Mitchell, Protein and Amino acid Requirements of Mammals, 1950).—I. Leitch.

5857

PFANDER, W. H. and TRIBBLE, L. F. Some effects of adding supplements of lysine, methionine and tryptophan to practical swine rations. *J. Animal Sci.*, 1955, 14, 545-555. [Univ. Missouri, Columbia.]

Trials were made with pigs fattened from weaning to 100 lb. liveweight. In one series the control groups received a basal ration which included vitamin B₁₂ and aureomycin, and had 18 or 16 per cent. protein supplied by tankage and soya bean oilmeal, reduced at 75 lb. liveweight to 16 and 14 per cent. The experimental groups got the basal ration plus 0.01 per cent. *L*-lysine, or 0.04 per cent. *DL*-methionine or both. The supplements increased growth rate and efficiency of feed conversion.

In another series the addition of 0.01 per cent. *L*-lysine, 0.04 per cent. *DL*-methionine or 0.04 per cent. *DL*-tryptophan increased growth rate and efficiency, but the amino-acids were not as effective in combination as given separately. When the antibiotic was excluded from the basal ration the stimulating effect of *L*-lysine was reduced.

On rations without animal protein neither *L*-lysine, *DL*-methionine nor a combination of the 2 increased growth rate, but efficiency was slightly improved.—T. D. Bell.

EGGERT, R. G., MAYNARD, L. A., SHEFFY, B. E. and WILLIAMS, H. H. Histidine—an essential

nutrient for growth of pigs. *J. Animal Sci.*, 1955, 14, 556-561. [Dept. Animal Husb., Cornell Univ., Ithaca, N.Y.]

Six piglets were weaned at 6 days old and kept on a stock milk-type diet based on casein for 8 days, after which 3 were given a basal diet very low in histidine and 3 the basal diet with histidine added. The basal diet contained purified amino-acids and diammonium citrate as the only sources of nitrogen. The growth of the piglets on the basal diet with histidine added was satisfactory but somewhat below the performance expected on a diet based on casein. These pigs were taken off the experiment after 18 days. After 22 days 2 pigs on the basal diet were growing only very slowly and were changed over to the diet containing histidine. The third pig was changed over to this diet on the 28th day. After the change-over the appetites and growth rates of these pigs increased greatly, although later in the experiment 2 died, one showing a hypertrophied heart. It was concluded that histidine is required for the normal growth of young pigs, although the requirement for it may be low.—I. A. M. Lucas.

GARD, D. I., BECKER, D. E., TERRILL, S. W., NORTON, H. W. and NALBANDOV, A. V. Sources of unidentified factors for the pig. *J. Animal Sci.*, 1955, 14, 532-544. [Illinois Agric. Exp. Stat., Urbana.]

Five experiments were made to study whether grass juice concentrate, a dried whey product, dried brewer's yeast, dehydrated alfalfa meal, menhaden fish solubles, or streptomycin residue contributed unidentified substances necessary for the rapid growth of pigs. In 3 of the experiments the basal diet consisted of purified ingredients and

N.A. and R., October 1955

in the remaining 2 it was a practical fortified maize and soya bean oilmeal ration. Weanling pigs with an initial weight of 23 to 33 lb. were used, and each experiment lasted 8 weeks.

Ten per cent. alfalfa meal in the diet depressed growth. This effect was apparently not due to the fibre of the alfalfa and may have been due to its saponin content. The streptomycin residue depressed growth when included in the purified diet but promoted growth when included in the practical diet. Neither dried brewer's yeast nor the dried whey product nor menhaden fish solubles appeared to contain unidentified growth substances for the pig, but grass juice concentrate produced significant growth responses and significant increases in feed consumption. This growth response also approached significance when adjusted for the difference in feed consumption. It is suggested that the oestrogens of the grass juice concentrate may have been responsible for its growth-stimulating property.—I. A. M. Lucas.

KRAUSE, H. and VOGEL, G. Über die Wirkung der APF-Zufütterung auf die Wachstumsgeschwindigkeit von Schweinen bei ausreichendem Eiweißangebot. [The effect of APF supplements on the growth rate of pigs with an adequate supply of protein.] *Arch. Tierernährung*, 1955, 5, 17-25. [Inst. Vet. Physiол., Humboldt Univ., Berlin.]

At a state pig feeding centre in the summer and autumn of 1954 pigs of both sexes and several breeds were fattened from 65 kg. to 100 kg. on a daily ration of fishmeal (56.9 per cent. digestible protein) 100, meatmeal (48.9 per cent. protein) 192.3, coarsely ground barley or rye (7.3 per cent. protein) 1050, kitchen waste of unknown and variable protein content 2000 and chalk 20 g., and from 100 to 120 kg. on the same with the cereals raised to 2550 g.; 671 pigs had a daily supplement of 15 g. Betapan, containing animal-protein factor and vitamin B₁₂, and 238 controls did not. The pigs were weighed in groups monthly and the results are shown graphically.

The pigs given Betapan reached 120 kg. in 3½ months, fully 4 weeks before the controls. Their daily gains were very steady during the first month or so and subsequently followed an S-shaped curve; those of the controls, at first lower, rose rapidly to a peak and then fell away. From a study of costs it was concluded that up to 80 kg. liveweight the supplement was justified.

WAHLSTROM, R. C. and WILSON, R. F. Feeding pigs trace-mineralized salt. *S. Dakota Agric. Exp. Stat. Circular* No. 108, June 1954, pp. 7.

Vol. 25, No. 4

In a trial with 2 groups of 15 pigs, initial liveweight 49 lb., fattened to slaughter weight of 225 lb., salt with trace elements added was compared with common salt. The mineral mixture was 2 parts bonemeal, 2 parts limestone and 1 part NaCl, which had trace minerals included with it for one group. The pigs were fed, and the mineral mixture was given, to appetite. There was no difference between the groups in rate or efficiency of gain.

A similar comparison was made in a second experiment, but in this case the pigs were lighter to start with, 33 lb., and the mineral mixture was of equal parts of bonemeal, limestone and salt, trace minerals being added as before. Two groups of 25 got the trace mixture and 2 groups did not. The pigs getting the trace minerals grew faster, but there was no advantage in efficiency. Possible reasons for the difference in results between the experiments are discussed.—T. D. Bell.

BARBER, R. S., BRAUDE, R., MITCHELL, K. G. and CASSIDY, J. High copper mineral mixture for fattening pigs. *Chem. and Indust.*, 1955, No. 21, 601. [Nat. Inst. Res. Dairying, Shinfield, Reading.]

Pigs fattened from 44 lb. liveweight for 18 weeks, given a mineral supplement supplying 250 p.p.m. Cu in their ration, gained slightly, but not significantly faster than control pigs on a standard diet of barley meal, fine wheat offal and whitefish meal. The difference was almost all during the first 8 weeks, and efficiency was also greater in this period. There was no difference in carcass grade, or in efficiency over the whole period. Further experiments are in progress.—T. D. Bell.

5865

BECKER, D. E., TERRILL, S. W. and NOTZOLD, R. A. Supplementary protein and the response of the pig to antibiotics. *J. Animal Sci.*, 1955, 14, 492-498. [Illinois Agric. Exp. Stat.]

In the first experiment 3 groups of weanling pigs were self-fed for 8 weeks on a diet of maize and soya bean oilmeal and 3 on a diet of maize and menhaden fishmeal. Both diets were supplemented with minerals and vitamins. One group on each diet was a control, one received 6 mg. chlortetracycline [aureomycin] per lb. diet and the third received 6 mg. of a mixture of chlortetracycline, procaine penicillin and streptomycin per lb. diet.

In the second experiment 4 groups of weanling pigs were self-fed, one on a diet of maize and soya bean oilmeal and 3 on a diet of maize and menhaden fishmeal which either had no supplement, or had 0.05 per cent. DL-tryptophan or 2.0 per cent. fish soluble solids added.

In experiment 1 the addition of chlortetracycline alone or the antibiotic mixture to the maize and soya bean diet improved rates of gain by 10.4 and 14.4 per cent., respectively, but when added to the maize and menhaden fishmeal diet they improved rates of gain by 38.9 and 83.3 per cent., respectively. Feed conversion efficiency was improved by the inclusion of either supplement in the diet of maize and menhaden fishmeal but by neither when added to the diet of maize and soya bean oilmeal. The antibiotic mixture was superior to chlortetracycline alone, this effect being more pronounced with the diet of maize and menhaden. In the absence of antibiotic pigs grew 73.6 per cent. faster on the diet of maize and soya bean oilmeal than on the diet of maize and menhaden fishmeal, but in the presence of antibiotic this difference was reduced to 8.3 per cent.

In experiment 2, pigs on the diet of maize and menhaden fishmeal, which contained 0.10 per cent. tryptophan, grew more slowly than those on the diet of maize and soya bean oilmeal, which contained 0.17 per cent. tryptophan, but their performance was improved up to the standard of the latter by the supplement of 0.05 per cent. DL-tryptophan. The addition of fish soluble solids to the diet of maize and menhaden fishmeal did not affect growth.—I. A. M. Lucas.

TAYLOR, J. H. and HARRINGTON, G. Influence of dietary antibiotic supplements on the visceral weights of pigs. *Nature*, 1955, 175, 643-644. [Agric. Res. Council, Field Stat., Compton, near Newbury, Berks.]

Pigs fattened to 200 lb. liveweight with a dietary supplement of penicillin had significantly heavier livers and non-significantly lighter small intestines than controls. With aureomycin the livers were lighter and the spleens and small intestines significantly lighter than in controls. The differences between the weights of small intestine and between the weights of liver on the 2 treatments were significant. Antibiotics did not affect the weight of stomach, caecum or large intestine. The total weight of viscera in the pigs getting penicillin was greater than in those getting aureomycin, which may have been the reason for the lower dressing percentage. The differences between the effects of the antibiotics suggest that they may have different modes of action.—T. D. Bell.

DAVEY, R. J., GREEN, W. W. and STEVENSON, J. W. The effect of aureomycin on growth and reproduction in swine. *J. Animal Sci.*, 1955, 14, 507-512. [U.S. Dept. Agric., Agric. Res. Centre, Beltsville, Md.]

Aureomycin at rates of 10, 50 or 100 mg. per lb. of a feed containing no animal protein was given to 3 generations of pigs. The higher levels had no adverse effect on reproductive performance as judged by number of pigs born per litter, birth-weight or weaning weight. Rate of liveweight increase in each generation from weaning to 220 lb. was significantly greater in the pigs getting 50 mg. aureomycin. There was no significant difference between the treatments in efficiency of feed utilisation, but the pigs getting 100 mg. aureomycin tended to eat less than those getting 50 mg., and ate slightly less per lb. liveweight increase.

5868

BOHMAN, V. R., HUNTER, J. E. and McCORMICK, J. The effect of graded levels of alfalfa and aureomycin upon growing-fattening swine. *J. Animal Sci.*, 1955, 14, 499-506. [Dept. Animal Husbandry, Univ. Nevada, Reno.]

A basal diet of ground milo with a protein supplement was modified by the inclusion of 10, 30 or 50 per cent. alfalfa meal and these 4 diets were given with and without 10 mg. aureomycin per lb. feed. The diets given before 120 lb. liveweight contained 4.3, 6.9, 12.6 and 17.6 per cent. crude fibre; after 120 lb., when the protein content was somewhat reduced, they contained 3.6, 7.0, 13.0 and 17.1 per cent. crude fibre. All rations were pelleted and self-fed and the pigs were slaughtered at about 200 lb. liveweight.

Average daily gains decreased with each increase in alfalfa content of the diet. Daily feed consumption was lower on the 2 higher levels of alfalfa, but this effect was not large enough to account for the differences in rates of gain. As the alfalfa content of the diet increased the feed conversion efficiency became worse, although pigs on rations containing 50 per cent. alfalfa consumed the least concentrate (milo and protein supplement) per lb. gain. The addition of aureomycin significantly increased rate of gain, but there was no significant interaction between level of alfalfa and presence of antibiotic, although there was a tendency for the response to antibiotic to decrease as the level of alfalfa rose. Aureomycin improved feed conversion efficiency at all levels of alfalfa.

Aureomycin had no effect on carcass quality measurements, but as the level of alfalfa rose the dressing percentage, depth of back fat, and percentage of belly bacon and fat back in the carcass significantly decreased, and the percentage of ham, shoulder and loin significantly increased. As the level of alfalfa rose the size of the stomach and large intestine, but not of the small intestine, increased. The size of these organs was not affected by dietary antibiotic, nor was the level of ascarid infestation.—I. A. M. Lucas.

HANSON, L. E., CARPENTER, L. E., AUNAN, W. J. and FERRIN, E. F. **The use of arsenilic acid in the production of market pigs.** *J. Animal Sci.*, 1955, 14, 513-524. [Univ. Minnesota.]

In the first experiment 4 groups of 10 pigs were used to compare a basal ration with the same ration plus supplements of 30, 60 or 90 g. arsenilic acid per ton feed for growth and fattening from weaning to 200 lb. liveweight. The experimental animals gained faster than controls, but not significantly, and there was no difference between groups in efficiency of feed conversion up to 125 lb. liveweight. Most of the difference in growth rate was in the first 4 weeks. After 125 lb. liveweight gains were not recorded because of an outbreak in all groups of lameness, the cause of which could not be diagnosed.

The second experiment was a comparison between 3 different protein levels all with 60 g. arsenilic acid per ton feed; a fourth group had free access to separate feeders, one containing ground maize and the other a high-protein balancer meal, so that in effect the animals chose their own level of protein. Arsenilic acid, 240 g. per ton, was included in the balancer meal. Differences in weight increase between the groups were not significant, and were not related to the protein levels.

In neither experiment did the treatments influence carcass quality, measurements or dressing percentage. Small amounts of arsenic were retained in muscle, liver and kidney, proportional to the amount of arsenilic acid given. When arsenilic acid was withdrawn 2 or 4 days before slaughter the amount of arsenic retained was greatly reduced.

T. D. Bell.

5870

HANSON, L. E., FERRIN, E. F. and SINGH, S. N. **The influence of arsenilic acid on protein requirements of growing pigs.** *J. Animal Sci.*, 1955, 14, 525-531. [Univ. Minnesota.]

Diets based on maize, soya bean oilmeal, tankage, linseed oilmeal, alfalfa meal, minerals and vitamins, compounded to contain either 18, 16 or 14 per cent. crude protein, were given to pigs from weaning to 125 lb. liveweight. For feeding from 125 to 200 lb. liveweight the crude protein content was reduced to 15, 13 and 11 per cent., respectively. Pigs were also given the ground maize and supplement free choice. The 3 fixed protein levels were given with and without an additional supplement of 60 g. arsenilic acid per ton of meal, and the free choice diet was given with and without the addition of 240 g. arsenilic acid per ton of protein supplement. There were thus 8 treatments. There were 2 replicates, with one group of 5 pigs on each treatment in each replicate.

Although pigs on the 18 or 16 per cent. protein diets grew the most rapidly during the first fortnight, protein level had no significant effect on average growth rate from weaning to 125 lb. A small advantage in rate of gain of pigs getting arsenilic acid was also not significant over this period. There was no significant effect of treatment on growth rate between 125 and 200 lb.

Feed conversion efficiency was slightly improved with arsenilic acid, but under the conditions of the experiment arsenilic acid did not have a protein-sparing effect, nor was there any evidence that it was toxic.

The pigs on free choice selected rations containing 14.4 and 15.2 per cent. crude protein before they reached 125 lb. and 12.8 and 12.2 per cent. crude protein after 125 lb.—I. A. M. Lucas.

5871

MORIMOTO, H., TAKAHASHI, A. and HOSHII, H. **[Effect of thiouracil upon the growth of young pigs and chickens.]** *Bull. Nat. Inst. Agric. Sci., Japan* [G], 1955, No. 10, 27-36. In Japanese; English summary.

The daily ingestion of 0.25 g. thiouracil by young pigs had no effect on growth. Higher amounts, 0.5 or 0.75 g., produced an increased rate of growth and better feed utilisation.

Administration of 0.15 g. daily to 3-month-old chickens increased their rate of growth from 4 to 8 weeks, after which growth rate fell.

Prolonged administration to pigs and administration to 2-month-old chickens had a bad effect on the thyroid. (From summary.)

BEESON, W. M., ANDREWS, F. N., PERRY, T. W. and STOB, M. **The effect of orally administered stilbestrol and testosterone on growth and carcass composition of swine.** *J. Animal Sci.*, 1955, 14, 475-481. [Dept. Animal Husb., Purdue Univ. Agric. Exp. Stat., Lafayette, Ind.]

Sixty pigs of average weight 45 lb. were divided into 6 groups which all had free choice of maize, protein supplement and mineral supplement. The following additional supplements were given: group 1, none; group 2, 60 g. terramycin per ton of protein supplement; group 3, 2.0 mg. stilboestrol per pig daily; group 4, terramycin in protein supplement and 2.0 mg. stilboestrol per pig daily; group 5, 20.0 mg. testosterone per pig daily; group 6, terramycin in protein supplement and 20.0 mg. testosterone per pig daily. The hormones were always given in the protein supplement. The pigs were slaughtered at about 225 lb.

Neither hormone significantly affected growth rate when there was no terramycin in the diet, but pigs receiving terramycin plus testosterone grew

significantly more slowly than those receiving only terramycin. Pigs receiving terramycin grew significantly faster than the control group. Neither hormone affected feed consumption or feed efficiency.

Stilboestrol increased mammary growth in both males and females and pigs receiving testosterone appeared somewhat trimmer in the sides and jowls.

Pigs receiving antibiotic but no hormone had the fattest carcasses. Testosterone increased the weights of the hams and picnics, and testosterone or stilboestrol given with terramycin resulted in heavier loins. There was a trend towards the production of leaner carcasses in both stilboestrol groups, but testosterone had a more marked effect in reducing the fat, and increasing the lean, content of the carcasses. Oestrogens were not deposited in the edible portions of the carcasses when stilboestrol was given.—I. A. M. Lucas.

5873

LUCAS, I. A. M. and CALDER, A. F. C. **The interaction between environment and level of feeding for pigs from weaning to bacon weight.** *J. Agric. Sci.*, 1955, **46**, 56-77. [Rowett Res. Inst., Bucksburn, Aberdeenshire.]

Trials were made in winter and summer to compare groups of pigs given high or low plane rations, and housed in good warm or bad cold and draughty pens. In this experiment high and low plane referred to the total digestible nutrient content of the rations, which had adequate protein, vitamins and procaine penicillin. The pigs grew and fattened from weaning to 200 lb. liveweight, with the exception of the groups on low plane rations in the bad piggery, which were removed from the experiment at 150 lb. liveweight, because their growth after 100 lb. was unsatisfactory. Altogether 168 pigs were used.

Growth and efficiency were worst affected from 45 to 100 lb. liveweight by low plane feeding in the bad piggery during the winter: on the high plane there was no ill effect in the same environment. The higher temperature in the bad piggery during summer seemed to be the reason for the better performance of the low plane pigs in it during the summer.

Though not statistically significant, there were indications that from 100 to 200 lb. liveweight growth was better in the high plane pigs in the bad piggery than in the good. Efficiency was better from 45 to 100 lb. liveweight in the good piggery on the low plane ration than on the high in either piggery, but from 100 to 200 lb. liveweight it was not better than in the pigs on high plane nutrition in the bad piggery.—T. D. Bell.

5874

SELF, H. L., GRUMMER, R. H. and CASIDA, L. E. **The effects of various sequences of full and**

limited feeding on the reproductive phenomena in Chester White and Poland China gilts. *J. Animal Sci.*, 1955, **14**, 573-592. [Dept. Animal Husb., Univ. Wisconsin, Madison.]

The effects of different sequences of full and limited feeding upon ovulation rates, embryo survival and other related phenomena were determined for Chester White (CW) and Poland China (PC) gilts. In 2 experiments the pigs were assigned to their treatments at 72 and 70 days of age, respectively. Each experiment was divided into 3 phases: (1) the prepubertal period, (2) the first oestrous cycle, and (3) the first 25 days of gestation after mating at the second heat.

In the first experiment 32 CW and 32 PC gilts were used. All were mated at the second heat and half were slaughtered 24 to 48 hr. later. The remainder were slaughtered on the 25th day after mating. Four lots each containing 4 CW and 4 PC gilts were fed to appetite during phase 1 and 4; similar lots received about two-thirds of the amount eaten by the full-fed pigs. During phases 2 and 3 two of the 4 lots on each treatment in phase 1 were fed to appetite and 2 lots received about two-thirds full feeding. The 4 treatments were termed FFF (full-fed during the 3 phases), FLL (full-fed during phase 1 and limited during phases 2 and 3), LFF (limited in phase 1 and full-fed in phases 2 and 3) and LLL (limited throughout). The diets contained 20 per cent. protein before 125 lb. liveweight and 15 per cent. protein thereafter.

In experiment 2, 37 CW and 37 PC gilts were all slaughtered at 25 days after mating at the second heat. The treatment groups, each containing equal numbers from each breed, were FFF, FFL, LFL and LLL.

The mean age of 225 days at puberty of the CW gilts in experiment 1 was significantly higher than the 206 days of age at puberty of the PC gilts, but this difference may have been affected by scouring in the FFF group of CW gilts. In experiment 2 there was no significant difference in age at puberty between breeds. In both experiments full-fed pigs were significantly older at puberty than limited-fed pigs and there were significant negative correlations between 154-day weights and ages at puberty. In experiment 2 the weights and ranges of weights at puberty of the full-fed pigs were significantly higher than for the limited-fed pigs. There was no significant relation between the day of birth in the farrowing season and age at puberty and there was no difference between breeds in length of first oestrous cycle, although it was more variable in CW gilts than in PC gilts.

Experiment 1 showed that limited feeding during the first oestrous cycle after full-feeding during the prepubertal period did not affect the

N.A. and R., October 1955

slight expected increase in ovulation rate from first to second heat of the PC gilts, although it caused a marked decrease in ovulation by the CW gilts. Nevertheless over all treatments CW gilts produced more ova at the second heat than PC gilts.

In experiment 1 the FFF and LFF groups both produced more ova at second heat than the FLL or LLL groups. In experiment 2 the FFF, FFL and LFL groups produced more ova than the LLL group. Both experiments thus indicated that full-feeding for about 3 weeks before second heat is sufficient to raise ovulation rate to that of pigs continuously full-fed.

Fertilisation rate was not affected by diet treatment, breed of gilt, breed of boar or individuality of the boar.

In neither experiment did the percentage survival of embryos at 25 days after fertilisation differ between breeds, but in experiment 2 a larger number of CW than of PC embryos survived. This was a reflection of their higher ovulation rate. Data pooled from both experiments showed that despite the lower ovulation rate associated with limited feeding there were larger litters because of a higher survival rate. This effect was seen in experiment 1 even with pigs changed to limited feeding only after puberty. In experiment 2 the largest number of living embryos was found in the LFL group.

Correlations showed that the individual gilts within a treatment group which gained fast immediately before or after breeding maintained a higher embryo survival rate than poorer-doing gilts within the same group. Second heat ovulation rate was negatively associated with survival rate.—I. A. M. Lucas.

KRÜGER, L. Über Versuche mit hohen Gaben von Lebertranemulsion. [*Experiments with large amounts of cod liver oil emulsion.*] *Futter u. Fütterung*, 1955, No. 50, 1-4. [Inst. Tierzucht Milchwirtsch., Univ. Giessen.]

Young pigs in 3 groups of 6 were given a basal ration of, per cent., wheatmeal [Weizenbollmehl] 33, oats 22, barley 42.5 increasing to 64.5, lucerne meal 2 and minerals 0.5, with 2 to 2.5 litres skimmed milk daily. The groups received no supplement or 30 or 60 g. cod liver oil emulsion per head daily mixed with the milk. The higher intake of cod liver oil reduced the time taken to reach 105 kg. from 122 to 105 days and produced no ill effect.

Calves given from 10 increasing to 30 or from 20 to 90 g. cod liver oil emulsion daily up to 13 weeks of age showed no ill effect, and the oil allowed skimmed milk to replace whole milk and thus reduced costs. Steers at 350 kg. liveweight

after high cod liver oil intakes did not differ from those given whole milk.

The ill effects reported from cod liver oil feeding by other workers could not be reproduced.

MEHNER, A. and SCHERRBACHER, H. Schweinemastversuche mit Pantomehl. [*Pig fattening experiments with Pantomehl.*] *Züchtungskunde*, 1955, 26, 297-302. [Inst. Tierzucht-lehre, Landwirtsch. Hochsch., Hohenheim.]

Pantomehl is a proprietary feed which contains, per cent., 30 fishmeal and 70 of a mixture of 50 parts concentrated fish press juice, 35 parts wheat bran and 15 parts soya bean meal. It has 33.6 per cent. digestible protein and 54.3 per cent. starch equivalent; cod meal has 54.0 and 59.5. In the first experiment there were 2 groups each of 6 pigs. The experimental rations were of chalk 1, cod meal 12, 6 or 3 and barley to 100, or Pantomehl 20, 10 or 5 and barley to 100. Protein allowance was the same in each interval. Mean daily rates of weight gain from, roughly, 25 to 100 kg. liveweight were 748 and 729 g., but the cod meal group grew much faster to 40 kg. and slightly faster from 40 to 70 kg. There was no difference in feed consumption per kg. weight gain.

In a second experiment there were 2 groups each of 7 pigs, roughly 30 kg. at the beginning. The allowances of cod meal and Pantomehl were reduced, for the first 2 time intervals, to 8 and 4.8, and 13.3 and 8 per cent. Mean daily rates of gain were 685 and 716 g. Again the cod meal group grew faster at first, but in the interval from 70 to 100 kg. the daily rates were cod meal 718 and Pantomehl 939 g. On the average the cod meal group ate 3.72 and the Pantomehl group 3.57 kg. feed per kg. weight gain, the advantage relating only to the last stage.—I. Leitch.

- HARRINGTON, G. and POMEROY, R. W. An analysis of carcass measurements of post-war British bacon pigs. *J. Agric. Sci.*, 1955, 45, 431-451. [Agric. Res. Council. Unit Animal Reproduction, Sch. Agric., Univ. Cambridge.]

Certain carcass quality measurements were taken on sides of bacon from carcass competitions of the National Pig Breeder's Association (NPBA) held between 1947 and 1953, on Danish No. 1 sides, and on a number of commercial sides from Britain, Denmark, Poland and Holland. Comparisons were made with carcass measurements from NPBA competitions held between 1932 and 1937.

Data from Large White carcasses in post-war NPBA competitions showed that sides from gilts were longer, had thicker bellies and larger "eye" muscles, and had smaller fat measurements than those from hogs. The size of the "eye" muscles gradually decreased between 1948 and 1952.

When compared with the pre-war measurements the carcasses at post-war NPBA shows were longer, had thicker bellies and smaller fat measurements, and were not as deep in the chest, but there was no change in size or shape of the "eye" muscle.

When compared with Danish No. 1 sides the British post-war show carcasses did not differ significantly in fat measurement over the shoulder, but they had 2.0 mm. more fat over the middle of the back. The British sides had thinner bellies, were deeper, had heavier fore ends and were shorter than the Danish.

When commercial sides were compared the Danish had lighter fore ends and heavier middles than the British. The Dutch were longer and

had lighter fore ends and heavier gammons than the British. The Polish sides were the shortest and had the lightest gammons.

Correlation coefficients were calculated to show the relation between different carcass measurements, and regression equations show the magnitude of the changes in carcass measurements with increases in carcass weight and carcass length.

- BROUGH, O. L. and SHEPHERD, G. Objective grade specifications for slaughter barrow and gilt carcasses. *Iowa Agric. Exp. Stat. Res. Bull.* No. 421, January 1955, pp. 228-244.

It was considered that a system of grading fat pigs by carcass evaluation would reflect their value on the market better than grading by liveweight and visual appraisal. A system is suggested based on a study of 600 carcasses of castrated males and gilts ranging in liveweight from 165 to 315 lb., or in carcass weights from 105 to 224 lb. The index of lean, i.e., the percentage of carcass weight represented by the weight of the high-value lean cuts, gives an accurate assessment of the value of the carcass. Back fat thickness and carcass length were the two objective measurements which had the highest correlations with the index of lean. When carcasses were graded on this system accuracy in foretelling the market value was good.

- ZOBIRSKY, S. E., LASLEY, J. F., BRADY, D. E. and WEAVER, L. A. Pork carcass evaluation. *Missouri Agric. Exp. Stat. Res. Bull.* No. 554, July 1954, pp. 60.

The relation between weight and measurements of different parts of the carcasses of 207 pigs slaughtered at about 200 lb. liveweight were studied. A close negative correlation existed between thickness of backfat, which could be measured either on the live pig by probe or on the carcass, and the proportion of highly priced cuts in the carcass. Dressing percentage could be estimated from measurements of body depth and width.

MORRIS, M. L. Nutritive requirements of the cat. 2. The feeding of cats exclusively on canned, sterilized foods. *North Amer. Vet.*, 1955, 36, 468-471. [Topeka, Kans.]

For part 1 see Abst. 3955, Vol. 24.

A group of 13 castrated male cats was fed on an adequate fresh meat diet with lard, yeast, calcium carbonate and skimmed milk, followed by the same diet in canned form. They were then divided into 4 groups, one continuing on the same diet while the others were fed on 3 representative commercial cat foods based on whole fish or fish by-products. Those on the control diet remained normal, but some of those on one of the fish diets showed emaciation, skin lesions and neurological signs. Injection of vitamin B₁ into one of the latter produced a gradual improvement, but the neurological signs remained even when the animal was given the control diet. It is concluded that a canned ration properly compounded can contain all the essentials for maintenance.—J. S. Thomson.

PEREL'DIK, N. SH. and TITOVA, M. I. Peredovoi opyt kormleniya vzroslykh norok. [Experiments in feeding adult mink.] *Karakul. Zverovodstvo*, 1954, 7, No. 2, 27-33. [All-Union Sci. Res. Lab. Fur Animals.]

A survey is made of methods of feeding practised by foremost sovkhoses, which enable mink to carry and rear their young without loss of weight. This loss is considerable on less efficient sovkhoses, and is evident in July after the pups have been weaned. One of the chief differences in the methods of feeding is the large amount of animal protein given to the animals throughout the year on the more advanced sovkhoses, the daily ration for adult mink being 25 to 30 g., corresponding to 125 to 150 g. raw meat.

Optimum daily standards and rations for adult mink at different seasons from which good results have been obtained are given as follows: July to August: 210 to 260 Cal., including 20 to 25 g. animal protein; September to December: 250

to 300 Cal., 23 to 28 g. animal protein; January to March: 250 to 290 Cal., 25 to 28 g. animal protein; April: 280 to 300 Cal., 27 to 32 g. animal protein. For the above periods the percentage of total energy derived from meat and fish is from 45 to 55, 45 to 65, 52 to 65 and 52 to 65; from milk 7, 5, 7 to 10, 10 to 12; from grain 32 to 42, 24 to 44, 21 to 28, 22 to 44; from vegetable 3, 3, 1 to 2, 1 to 2; and from cod liver oil and yeast 3, 3, 3 to 10, 3 to 10.

During the summer animals may die of enlarged liver, but milk or cereals up to 15 per cent. of the energy value of the diet appears to prevent this.

During lactation the standard ration of the dam should supply 200 Cal., to which is added a supplement, per pup, of 10 Cal. at the beginning of lactation, rising to 170 Cal. towards the end.

H. Scherbatoff.

5889

ZHARKOV, I. V. Osobennost' letnego kormovogo rezhima losya v Zhigulyakh. [The peculiarities of the summer feeding habits of the elk in Zhiguli.] *Byull. Mosk. Obsch. Ispytatel' Prirod., Otdel Biol.*, 1954, 59, No. 5, 3-8.

The main feed of the elk from May to August consists of herbaceous plants. During May and June only the vegetative parts are eaten. In August only the generative organs of plants, such as flowers and the ears of cereals, are eaten. In the summer herbaceous plants form 80 per cent. of the total eaten, only 20 per cent. of the total consisting of the shoots and young green leaves of trees such as the sycamore. In August the percentage of woody plants goes up to 40 and that of herbaceous plants falls to 60 of the total. Water plants which usually form part of the elk's feed in other parts of the U.S.S.R. are completely absent in this district, where the elk is at the southernmost limit of its distribution, on the borders of the forest steppe and the steppe zones. The principal difference in the winter feeding habits of the elk and the spotted deer is that when the ground is covered with snow the elk feeds entirely on the twigs and bark of trees; the spotted deer feeds on the grass which it digs for under the snow.

H. Scherbatoff.

5890

BELOUS, I. S. Peredovoi olenovodcheskii sovkhos "Maikhe". [The first-class deer sovkhos

"Maikhe".] *Karakul. Zverovodstvo*, 1954, 7, No. 5, 54-55.

The Maritime Province, which is the East part of the U.S.S.R. in Asia, is the native habitat of the spotted deer, 80 per cent. of all those in the U.S.S.R. being found there.

This particular sovkhos, notwithstanding its being one of the worst situated for obtaining fodder, of those in the Far East Animal Trust, was able in the first 3 years of the 5-year-plan to increase the herd of deer by 25 per cent., by giving the deer 1½ times more coarse fodder and 2½ times more succulent fodder than in the rest of the Trust. The fodder was also carefully prepared, the coarse fodder being cut up and steamed with a mixture of concentrates; bones were given, and a mineral supplement and salt bricks were always available.

During the winter the deer were kept at pasture divided into paddocks which were grazed in rotation. Oats, soya bean and Japanese millets were sown for feed. The young deer gradually became domesticated, 900 being pastured on free range in charge of herdsmen, thus gradually relieving the farm of the necessity of building fences. The management of the herd was exactly like that of a flock of sheep.—H. Scherbatoff.

5891

RYASHCHENKO, L. P. Iz opyta past'by pyatnistykh olenei pastukhami v sovkhozakh Dal'zverostresta. [The experience of pasturing spotted deer on the state farms of the "Dal" Fur Bearers Trust.] *Karakul. Zverovodstvo*, 1954, 7, No. 6, 39-42. [Supporting Point All-Union Sci. Res. Lab. Fur Animals and Pantiferous Deer Management.]

This is a discussion and criticism of the methods employed on different sovkhoses for training spotted deer for pasturing on free range by herdsmen.

The domestication of spotted deer is a matter not only of a preliminary training in fenced yards and enclosures with moveable fencing and sheds for shelter but of the personality of the herdsmen. Regular feeding has not been properly organised in most sovkhoses and young deer are often left without feed at night, when green fodder should be supplied. Regular rotation of pastures is also essential.—H. Scherbatoff.

TAYLOR, J. I. The rearing of an African elephant in captivity. *Vet. Rec.*, 1955, 67, 301-302. [Animal Health Res. Centre, Entebbe, Uganda.]

A 2-week-old orphan elephant was successfully reared for a week on 20 pints daily of cow's milk, supplying 13.2 oz. protein, 19.6 oz. lactose and 14.4 oz. fat, fortified with 1.8 oz. protein as calcium caseinate, 12 oz. lactose and 5 oz. cream. This

mixture was thought to resemble the composition of elephant milk, although wide variations in composition were noted in the literature. Two tablespoonfuls of blackcurrant juice, 2 yeast tablets and 1 oz. cod liver oil were also given daily. The animal gained 25 lb. by the end of the week and scouring had ceased. Owing to expense of upkeep the animal had to be transferred to a Zoological Society collector in Nairobi, and it died shortly afterwards of gastro-enteritis.—J. S. Thomson.

5893

NATIONAL RESEARCH COUNCIL, U.S.A. Nutrient requirements for domestic animals. 9. Nutrient requirements for rabbits. *Publ. No. 331*, 1954, pp. 12.

The nutrient requirements of the rabbit have not been investigated as fully as those of other domestic animals. From the available information the suggested requirements of total feed, total digestible nutrients (TDN) and digestible protein for maintenance, normal growth, fattening, gestation and nursing, including a litter of 7, are tabulated for rabbits weighing from 4 to 15 lb. These requirements are also presented as total feed as a percentage of bodyweight and TDN and digestible protein as percentages of total feed. The requirements for minerals and vitamins are not precisely known. Qualitatively, mineral requirements are probably the same as those of other animals, but quantitatively only Mn and Mg have been estimated. Of the vitamins, nicotinic acid and vitamin E have been estimated. The synthesis of other B vitamins in the caecum and the habit of coprophagy indicate that dietary supplements of these vitamins are not necessary, and from the available evidence it would appear that vitamin C is also not required in the diet.

In rabbits deficiencies of energy, protein, minerals or vitamins are usually small, and clearly defined indications are rarely seen. Salt is often lacking in normal feeds, and it is advisable to include some in the ration. Signs of deficiency of vitamins A and E are the same as in other animals, and rickets, presumably similar to that encountered in other animals, results from deficiency of vitamin D and faulty Ca:P ratio, though a dietary supplement of the vitamins is not usually necessary. Nicotinic acid is essential in the diet, and "egg white disease", thought to be a sign of biotin deficiency, has been encountered.

Suitable concentrates and roughages are enumerated. These include the grains, oilseed meals, grass and legume hays, fresh grass and roots. Cottonseed meal should not be given to the young. Unextracted oilseeds and animal protein supplements are unpalatable. Full feeding should be allowed only to pregnant and nursing does and animals being fattened for meat. Pelleted and

purified rations are discussed and there is a table giving the digestible crude protein and TDN of the most common feeds used in rearing rabbits.

5894

ELENEK, YA. Vliyanie kormleniya kukolkoi tutovogo shelkopryada na plodovitost' samok, rost i razvitiye molodnyka krolikov. [The effect of feeding silkworm chrysalides to rabbits on fertility and the growth and development of the young.] *Karakul. Zverovodstvo*, 1954, 7, No. 6, 48-50. [V.I. Ulyanov-Lenin Univ., Kazan.]

Giving silkworm chrysalides to rabbits in summer and winter helped to increase the number of rabbits in a litter, the number of survivals and also the growth and development of the young. Rabbits of 1 to 2 months should be given 6 g. daily and of 3 to 4 months 8 to 12 g. During the winter does were given 15 g. per head daily in addition to their winter ration of oats, bran, potatoes and

clover hay. The milk yield of the does also was increased.—H. Scherbatoff.

5895

LEONTYUK, S. V. Protivokoksidioznye ratsiony dlya molodnyaka krolikov. [Anti-coccidiosis rations for young rabbits.] *Karakul. Zverovodstvo*, 1954, 7, No. 5, 56-59. [Sci. Res. Inst. Rabbit and Animal Management.]

The best anti-coccidiosis ration for young rabbits was a ration rich in green food (70 per cent. of the nutrient value of the total ration), containing not more than 30 per cent. concentrates (oats and oilcake) and not more than 10 per cent. digestible protein of the total number of feed units. A small amount of "acidophilin", 50 g., may be added. This ration should be used from the moment rabbits leave the nest up to 3 to 4 months.

"Acidophilin" is effective in rabbit coccidiosis.

H. Scherbatoff.

POULTRY

GROWTH AND FATTENING

5896

AXELSSON, J. Influence of some factors on hatchability of chicken eggs and on growth rates of embryos and chicks. *Kgl. Lantbrukshögsk. Ann.*, 1954, 21, 81-103. [Inst. Animal Nutrit.]

The loss in weight of eggs during the 24 hr. after laying when held at 20° C. (68° F.) was a good indication of their hatchability, the highest percentage hatched being from eggs losing 100 to 160 mg. The size of the egg also influenced hatchability. The optimum weight was about 56.4 g., and hatchability was less in larger or smaller eggs, with great variation between individuals.

There was a direct relation between the size of the egg and the weight of the newly hatched chicken, 10 g. increase in egg weight giving 6.3 g. increase in the weight of the chicken. The weight of the chicken was about 66.7 per cent. of that of the egg. An increase of 10 g. in egg weight caused an increase of 17.3 g. in the weight of the chicken at 6 weeks of age. The hatching weight and the weight at 6 weeks were related so that an increase of 10 g. in the former gave an increase of 29.9 g. in the latter.

Three feed mixtures were used to rear the chickens. They contained 5.4, 7.0 and 8.6 per cent. crude fibre, with 2801, 2670 and 2539 Cal. metabolisable energy per kg., but were otherwise equal. The proportion of fibre in the ration did not affect mortality. Digestibility of all constituents decreased as fibre increased. Weight increases to 6 weeks old were lowest with the high-

fibre ration, and it was calculated that the optimum level of crude fibre would be 5.75 per cent. The chickens were most efficient in feed conversion at the lowest level of fibre. When carcasses were analysed at hatching all chickens had about 59 Cal. energy in the body tissues. At 6 weeks of age the greatest energy content was in the group getting 7.0 per cent. crude fibre. The low, medium and high groups retained 17.0, 18.5 and 17.9 per cent. of the metabolisable energy of the feed, respectively, and it was calculated that the best retention of energy would be at a crude fibre level of 7.26 per cent.—T. D. Bell.

FRANSEN, J. M., ANDREWS, F. N. and CARRICK, C. W. The effect of plane of nutrition on growth and sexual development of Barred Plymouth Rock cockerels. *Poultry Sci.*, 1955, 34, 205-209. [Purdue Univ., Agric. Exp. Stat., Lafayette, Ind.]

A strain of Barred Plymouth Rock cockerels that had been selected for their rapid growth and early maturity was reared from hatching to 10 weeks of age on ration 1, meat-and-bone scraps 12, dried buttermilk 4, lucerne meal 3, wheat bran 15,

wheat middlings 15, a vitamin D concentrate and yellow maize meal to 100; or ration 2, condensed fish solubles 3, soya bean oilmeal 36, maize gluten meal 6, dried whey 3, minerals 3.5, choline, nicotinic acid, riboflavin, calcium pantothenate, vitamin B₁₂, a vitamin A and D concentrate, aureomycin and yellow maize meal to 100.

On ration 1 the birds finished with a mean weight of 918 g.; on ration 2 they reached this weight in their eighth week and finished with a weight of 1318 g. The mean weights of testes on the 2 rations at 10 weeks of age were 1.40 and 1.68 g., respectively, a non-significant difference. Expressed as a percentage of bodyweight, the testes of the birds receiving ration 1 were heavier than those of the faster-growing birds on ration 2. Histological examination of the testes showed that about 60 per cent. of the cockerels in each group had spermatids, sperm heads or spermatozoa.

There is no evidence, therefore, that the ration which gave a faster rate of growth in the first 10 weeks of life had any corresponding effect on sexual development.—K. J. Carpenter.

5899

PATRICK, H. Influence of protein source on consumption and excretion of water and excreta voided by broiler chicks. *Poultry Sci.*, 1955, 34, 155-157. [Poultry Dept., Univ. Tennessee, Knoxville.]

Meat-type chicks were fed in their sixth week on a commercial mash containing 21 per cent. crude protein. They were reared in wire-floored cages in a room kept at 70° F. and drank 1.9 lb. water per lb. of feed consumed. Other birds were fed on the same rations supplemented with either meat scraps, fishmeal, soya bean oilmeal, groundnut meal, cottonseed meal, casein or milk albumin at the expense of yellow maize meal so as to raise the crude protein content to 28 per cent. On these rations the consumption of water ranged from 1.6 to 2.1 lb. per lb. of feed consumed.

From this and a further experiment it is concluded that protein concentrates do not always increase the water requirement of broilers.

FINDRIK, M. and SREMAC, Z. Djelovanje animalnih proteinskih koncentrata, sojine ekstrakcije prekrupе i metilthiouracila na porast tjelesne težine i iskorišćivanje hrane kod tova pilića. [The effect of animal protein concentrates, soya bean oilmeal and methylthiouracil on the increase of bodyweight and utilisation of feed in fattening chickens.] *Vet. Arhiv*, 1955, 25, 161-166. English and German summaries.

Six groups of cockerels, aged 10 weeks, were fattened on a basal ration of ground maize 100, ground barley 100 and ground oats 50, with additions of 50 parts each of fishmeal, meat-and-bone meal, powdered whole milk, bloodmeal, and soya bean meal alone or with 0.05 per cent. methylthiouracil.

The highest rate of gain was obtained with fishmeal, followed by dried milk and meat-and-bone meal; that obtained with bloodmeal was significantly less. The poorest results were with soya bean meal, and the addition to it of methylthiouracil had no significant effect. (From summary).

FOX, M. R. S., ORTIZ, L. O. and BRIGGS, G. M. Toxicity of ethionine in the young chick. *J. Agric. Food Chem.*, 1955, 3, 436-438. [Lab. Biochem., Nat. Inst. Arthritis and Metabol. Dis., Pub. Health Serv., Bethesda, Md.]

Two synthetic diets were used in trials with chickens from hatching to 4 weeks of age. One contained 0.4 per cent. methionine and one had none. The addition of 0.2 per cent. ethionine to the first of these diets depressed growth and efficiency. Cystine, 0.3 per cent., further depressed growth and 1.0 per cent. choline lessened the depression due to ethionine. A higher level of choline, 1.5 per cent., was not quite as effective as 1.0 per cent. In combination, 0.3 per cent. cystine and 1.0 per cent. choline counteracted one another.

On the diet without methionine, the addition of 0.4 per cent. of that amino-acid improved growth and efficiency, which were then depressed by 0.1 per cent. ethionine. With cystine and choline the effects were the same as with the other diet. Elemental sulphur also increased the depression due to ethionine, and 0.18 mg. vitamin B₁₂ per kg. diet did not prevent it.

When 0.2, 0.3 or 0.4 per cent. methionine was added to the diet already containing 0.4 per cent., growth was progressively depressed. Again it was found that ethionine depressed growth on the ration with 0.4 per cent. methionine, but it did not prevent the depression caused by excess methionine. In this trial male and female were compared: there was no difference between the responses.

These trials refer only to young chicks; the findings may not be applicable to adult birds.

DONOVAN, G. A., JOHNSON, E. L., BALLOUN, S. L. and PHILLIPS, R. E. The long range effect of low level methionine supplementation in growing turkey rations. *Poultry Sci.*, 1955, 34, 251-256. [Dept. Poultry Husb., Iowa State Coll., Ames.]

Broad Breasted Bronze turkeys were reared from hatching to 24 weeks of age in indoor pens on an all-mash system. Mash 1, to 8 weeks of age, was of fishmeal 2.5, meat-and-bone scrap 2.5, soya bean oilmeal 48, lucerne meal 4, minerals 5.5, a vitamin supplement (including choline 0.1) and yellow maize meal to 100. Mash 2 and 3, to 16 and 24 weeks of age, were of similar constituents with less of the protein concentrates. The calculated crude protein contents of the mashes were 28.6, 22.0 and 17.0 per cent., and their methionine contents, estimated microbiologically, were 0.41, 0.34 and 0.28 per cent.

The male birds receiving these diets finished with a mean liveweight of 20.9 lb.; others that received the same rations each supplemented with 0.025 or 0.05 per cent. DL-methionine weighed 21.2 and 21.9 lb. The weights for a parallel series of females were 13.9, 13.8 and 14.5 lb. The feed conversion ratios for the groups, males plus females, were 4.58, 4.40 and 4.23.

In a parallel trial with Beltsville Small White turkeys the addition of 0.05 per cent. DL-methionine again gave faster growth to market weight and an improvement in the efficiency of feed conversion. Results with the smaller supplement were inconclusive.

In each trial additional treatments were tested in which, from 8 weeks onwards, birds had free choice of a grain mixture, calculated to contain 9.9 per cent. crude protein and 0.22 per cent. methionine, and a balancer mash, containing 29.6 per cent. crude protein and 0.42 per cent. methionine, or the same mash supplemented with methionine as before. Under these conditions the supplements were without any consistent effect; this would be explained if the birds ate a high proportion of mash to grain so that their intake of methionine, without the supplement, was equal to that of the birds that received the all-mash rations plus methionine.

It is concluded that the value of methionine supplements in turkey feeding results from the correction of a dietary deficiency and that there is no need to assume a special property of free as opposed to bound methionine.—K. J. Carpenter.

Vol. 25, No. 4

arginine and glycine on the growth of chicks receiving complete, purified diets. *Poultry Sci.*, 1955, 34, 186-190. [Dept. Biochem., Coll. Agric., Univ. Wisconsin, Madison.]

Groups of 15 chicks were housed in wire-floored cages and fed from hatching to 4 weeks of age on a control ration made up of casein (alcohol-extracted) 18, gelatine 10, minerals 6, soya bean oil 0.5, L-cystine 0.5, vitamin B₁, riboflavin, nicotinic acid, vitamin B₆, calcium pantothenate, choline chloride, biotin, inositol, folic acid, vitamin B₁₂, p-aminobenzoic acid, 2-methyl-1:4-naphthoquinone, α -tocopherol acetate and sucrose to 100; they also received a fish oil, rich in vitamins A and D, by dropper. In 4 trials these groups weighed 273, 300, 315 and 262 g.

Parallel groups that received a similar ration in which the gelatine was omitted and 1 per cent. of L-arginine hydrochloride and 1.5 per cent. of glycine were included showed similar rates of growth. Where dextrin was used to replace sucrose, or when the rations were supplemented with an antibiotic mixture of bacitracin and procaine penicillin, growth was from 2 to 8 per cent. faster with gelatine than with the mixture of arginine and glycine.—K. J. Carpenter.

ROSENBERG, H. R., WADDELL, J. and BALDINI, J. T. The effect of added methionine in broiler diets containing high levels of fish meal. *Poultry Sci.*, 1955, 34, 114-117. [Stine Lab., E.I. du Pont de Nemours and Co., Inc., Newark, Del.]

Duplicate groups of New Hampshire chickens were fed to 8 weeks of age on each of 3 experimental rations containing 21.5 per cent. crude protein. Ration A was of soya bean oilmeal 35, maize oil 3, minerals 3.5, a complex vitamin supplement, procaine penicillin and yellow maize meal to 100. Rations B and C were similar but included 5 and 15 per cent., respectively, of fishmeal added at the expense of soya bean oilmeal, and with adjustments in the levels of minerals and maize meal. The finishing weights on these rations were 1317, 1298 and 1318 g. The same rations were also given with a supplement of 0.05 per cent. DL-methionine, and the final weights were 1, 4 and 2 per cent. heavier than with the rations unsupplemented.

Both by calculation, and by actual estimation, ration A had the lowest content of cystine plus methionine, so that the failure to obtain a greater response by adding methionine to this ration than by adding it to those of higher sulphur amino-acid content suggests that the mechanism by which free methionine stimulates growth is not the correction of a simple dietary deficiency.

FISHER, H., SCOTT, H. M. and JOHNSON, B. C.
The role of glycine in chick nutrition. *J. Nutrition*, 1955, 55, 415-430. [Div. Animal Nutr., Dept. Animal Sci., Univ. Illinois, Urbana.]

Chicks were housed in wire-floored cages and fed from 3 to 25 days of age on a control ration of casein 18, maize oil 3, cellulose 3, L-arginine hydrochloride 1, glycine 1, DL-methionine 0.3, choline chloride 0.2, minerals 5.3 and glucose to 100, with supplements of the known vitamins with the exception of nicotinic acid and vitamin B₁₂. They finished with a mean weight of 269 g. Parallel groups of birds that received the same ration supplemented with either 4 per cent. of glycine, 40 µg. vitamin B₁₂ per kg. or 200 mg. nicotinic acid per kg., singly, 2 supplements at a time or all 3 supplements together, finished with weights ranging from 285 to 315 g. Of the 3 supplements, glycine appeared to have the greatest effect. The glycine supplement also had a striking effect in raising the efficiency of feed conversion to 0.66 g. per g. feed as compared with 0.46 for the chicks receiving the control ration.

Since it had been expected that the addition of glycine to the control ration would depress growth, instead of stimulating it, the same supplement was added to a second control ration made up of Drackett (soya bean) protein 30, maize oil 3, cellulose 3, L-cystine 0.25, choline chloride 0.2, minerals 5.3, glucose to 100 and the same vitamin supplement with the addition of nicotinic acid and vitamin B₁₂. Birds receiving this ration weighed 365 g. at 26 days of age, and others receiving the same ration supplemented with glycine weighed 369 g. The addition of 4 per cent. DL-methionine had a slight growth-depressing effect in each case.

Although the addition of glycine did not affect the rate of growth in the second experiment it did improve both the efficiency of feed conversion and the rate of feathering; the glycine content of the feathers was unchanged.—K. J. Carpenter.

DYMSZA, H., BOUCHER, R. V. and MCCARTNEY, M. G. The influence of fiber content and physical form of the diet on the energy requirements of turkeys. 1. Studies with turkey poults. *Poultry Sci.*, 1955, 34, 435-439. [Dept. Agric., Pennsylvania State Univ., University Park.]

Groups of 20 male turkey poults were reared on 3 experimental rations containing 5, 10 and 15 per cent. of crude fibre, each being given both in the form of mash and of "crumbles", i.e., granulated feed with the fine particles sifted out. Each ration contained 28 per cent. of crude protein and incorporated fishmeal, yeast and whey with a supplement of procaine penicillin. The 3 rations contained 3.6, 21 and 38 per cent. of oat hulls, and soya bean oilmeal and yellow maize meal formed the other variables.

The birds receiving the 3 mash rations finished with mean weights of 2025, 1761 and 1066 g.; the corresponding figures with "crumbles" were 2236, 1929 and 1681 g. The average feed consumptions per head of the mashers were 5.66, 5.54 and 4.54 kg., and of the crumbles 5.77, 5.68 and 6.13 kg. These figures indicate that the depression of appetite with increased fibre that was clearly shown in the mash series did not occur with the "crumbles". The increased consumption of the high-fibre crumbles did not, however, compensate for their lower productive energy value (as calculated from the tables of Fraps).

Variability in weight gain between individuals within a group was considerably greater among those receiving the high-fibre mash than in the others. Replication of the trial with females showed the same trend of results with slower absolute growth throughout.—K. J. Carpenter.

RUNNELS, T. D. Animal fat in combination with various other ingredients in broiler rations. *Poultry Sci.*, 1955, 34, 140-144. [Dept. Animal and Poultry Indust., Univ. Delaware, Newark.]

The use of detergents instead of soap has now resulted in a surplus of animal fats. To utilise this surplus it is suggested that animal fats might be incorporated in poultry rations.

Experiments were made with young cockerels on a control ration of yellow maize meal and soya bean oilmeal to which additions were made of 3 per cent. animal fat, 1.5 per cent. dried sardine fish solubles, 6 per cent. condensed whey and 2.5 per cent. dehydrated alfalfa meal, individually and in all possible combinations.

Paired data for growth to 10 weeks showed non-significant increases in growth rate for all the supplemented groups as compared with controls. For the group receiving animal fat there was a saving of about 11 per cent. in feed efficiency.

J. S. Thomson.

SIEDLER, A. J., SCHEID, H. E. and SCHWEIGERT, B. S. Effects of different grades of animal fats on the performance of chicks. *Poultry Sci.*, 1955, 34, 411-414. [Div. Biochem., Amer. Meat Inst. Found., Chicago, Ill.]

N.A. and R., October 1955

In each of 2 experiments a group of 25 cockerels was fed to 10 weeks of age on a mash made up of soya bean grits (solvent-extracted) 16, meat scrap 8, menhaden fishmeal 3, bloodmeal 2, maize gluten meal 2, lucerne meal 2, butyl fermentation solubles 1, iodised salt 0.5, fish oil 0.3, manganese chloride, nicotinic acid and yellow maize meal to 100. The 2 groups finished with mean weights of 1280 and 1300 g., and feed conversion efficiencies of 0.40 and 0.42 g. gain per g. feed.

Parallel groups received the same rations supplemented with either 3 or 6 per cent. of white, yellow or brown grease or prime or No. 2 tallow. All these fats had been selected on the basis of free fatty acid content and stabilised with an antioxidant mixture containing butylated hydroxyanisole. The free fatty acid content of the 5 samples was 3, 59, 17, 3 and 31 per cent., respectively, and none contained more than 1.7 per cent. of unsaponifiable material. Finishing weights ranged from 1220 to 1410 g. in the first trial, and from 1240 to 1370 g. in the second. These weights did not differ significantly from those of the control groups, nor was there any effect on feed conversion efficiency. A final treatment with a 3 per cent. supplement of stabilised free fatty acids (from hydrolysis of white grease) was also without effect.

The eating quality of the birds was excellent from every treatment; some judges considered that the use of fats in the diet had increased the juiciness of the birds. From analysis of excreta it was concluded that all the fats used were highly digestible.—K. J. Carpenter.

DARROW, M. I. and ESSARY, E. O. **Influence of fats in rations on storage quality of poultry.** *Poultry Sci.*, 1955, **34**, 427-431. [Res. Labs., Swift and Co., Chicago, Ill.]

In the first trial a normal broiler ration given to New Hampshires from day-old to 10 weeks of age was compared with the same ration plus 5 per cent. tallow or 5 or 10 per cent. hydrolysed soya bean oil, and in the second trial the additions were 5 or 10 per cent. hydrolysed cottonseed oil or 10 per cent. hydrolysed soya bean oil. The birds

were all killed at 10 weeks of age, dressed and stored in a refrigerator for 6 or 9 months, when organoleptic and chemical tests were made. The experimental diets did not have any detrimental effect on taste or acceptability after either 6 or 9 months' storage, and peroxide values did not indicate any rancidity in skin or visceral fats of the carcasses.—T. D. Bell.

O'ROURKE, W. F., PHILLIPS, P. H. and CRAVENS, W. W. **The phosphorus requirements of growing chickens and laying pullets fed practical rations.** *Poultry Sci.*, 1955, **34**, 47-54. [Wisconsin Agric. Exp. Stat., Madison.]

The results of 3 experiments showed that from hatching to 3 weeks of age chickens receiving a practical basal ration supplemented with bonemeal as the source of inorganic P required at least 0.73 per cent. P for optimum growth. From 4 to 10 weeks 0.60 and from 10 weeks to sexual maturity 0.42 per cent. was adequate.

In a further experiment cockerels required 0.75 per cent. P in the ration from 0 to 8 weeks old, but for pullets 0.60 per cent. was sufficient when growth was the criterion. Date of first egg was not retarded when only the basal ration containing 0.32 per cent. P, nearly all from plant sources, was given, and although the birds did not grow as well in the early stages as those getting a higher percentage of P, at 42 weeks old they had reached normal weight for this age. Egg production was maintained on a basal ration containing 0.43 per cent. P. No account was taken in these experiments of the Ca:P ratio; in some of them Ca was given to appetite.—T. D. Bell.

FANGAUF, R., KLEIN, F. W. and BARLÖWEN, G. v. **Futtermischungen mit verschieden hohen Fettgehalten als Bestandteil des Kükenfutters. [Bonemeal with different fat contents as a component of chick rations.]** *Arch. Geflügelk.*, 1955, **19**, 186-190. [Lehr- und Versuchsanst. Kleintierzucht, Kiel, Steenbek.] English summary.

Five groups of 30 chickens received from hatching to 8 weeks of age a basal diet with a mineral mixture or with 3 per cent. bonemeal. The first 3 bonemeal samples contained 7, 4 or 1 per cent. fat and the fourth was a decalcified and defatted feeding bonemeal.

There was no ill effect from the high-fat bonemeal.—D. Duncan.

5917

KRATZER, F. H., DAVIS, P. N. and MARSHALL, B. J. **Cottonseed meal in rations for starting poults, growing turkeys and turkey breeder hens.**

Poultry Sci., 1955, **34**, 462-468. [Dept. Poultry Husb., Univ. California, Davis.]

Turkey poults were reared intensively from 2 to 29 days of age on a ration of cottonseed meal 45, dried whey 2, lucerne meal 5, minerals, vitamins, antibiotics and mixed cereals to 100; their daily gain was 4.59 per cent. This ration had a calculated lysine content of 1.0 per cent.; birds that received the same ration supplemented with 0.5 per cent. DL-lysine hydrochloride and 0.1 per cent. DL-methionine had a mean daily gain of 5.52 per cent. A further group that received the control ration with half of the cottonseed meal, which was a commercial sample prepared by screw pressing, replaced by soya bean oilmeal had a mean daily gain of 5.89 per cent.; with a supplement of 0.1 per cent. DL-methionine the gain was 5.69 per cent.

In a second trial of the same type, in which one-quarter, one-third, one-half, two-thirds and three-quarters of the cottonseed meal was replaced by soya bean meal in the control ration, mean daily gains were 5.61, 5.69, 5.80, 5.83 and 5.93 per cent., respectively.

Turkeys were also brought to market weight on similar rations with progressively decreasing levels of protein. In each treatment the percentage of fishmeal was decreased from 5, to 8 weeks of age, to 1.25 from 19 weeks onwards. With cottonseed meal as the sole vegetable protein concentrate, from 40 to 12 per cent., the mean finishing weights at 28 weeks of age were 9500 and 6800 g. for males and females. These figures did not differ significantly from those obtained with soya bean meal as the sole vegetable protein concentrate, although growth with the cottonseed meal had been slower in the first 4 weeks. Similarly, there was no "white-barring" of the feathers in either group after 16 weeks although this was almost universal for the first 8 weeks among the poults receiving cottonseed meal.

Lastly, turkey hens were penned intensively and fed on a ration of cottonseed meal 14.4, fishmeal 2.5, lucerne meal 5, dried whey 5, minerals, vitamins and mixed cereals to 100. The birds were inseminated artificially; after 3 months on the ration the mean hatchability of the fertile eggs laid was 58 per cent. Further groups that received similar rations with half or all of the cottonseed replaced by soya bean oilmeal gave corresponding hatchability figures of 49 and 54 per cent. Sample eggs from both the groups receiving cottonseed were found to develop characteristic discolouration of both yolks and whites.

It is considered that the maintenance of normal hatchability with 14 per cent. cottonseed meal in the ration may be attributed to the use of a batch of meal of particularly high quality.

5918

COUCH, J. R., CHANG, W. Y. and LYMAN, C. M. The effect of free gossypol on chick growth. *Poultry Sci.*, 1955, **34**, 178-183. [Dept. Biochem. Nutrit., Texas Agric. Exp. Stat., Agric. and Mech. Coll. System, College Station.]

Graded levels of free gossypol in the form of pigment glands were given to chicks to test their tolerance. When free gossypol formed 0.06 per cent. or less of the diet there was no detrimental effect on growth rate, mortality or feed efficiency.

The addition of 1 per cent. DL-lysine hydrochloride increased the rate of growth at all levels of free gossypol, but did not change the tolerance for gossypol.—D. H. Shrimpton.

5919

GERRY, R. W. High efficiency rations for poultry. *Maine Agric. Exp. Stat., Bull. No. 523*, January 1954, pp. 26.

After a series of testing trials in which meat-type chicks were raised to 12 weeks of age a ration is recommended consisting of soya bean oilmeal 22.5, fishmeal 5, distiller's dried solubles 2.5, maize gluten meal 2.5, a butyl fermentation product rich in riboflavin 1, lucerne meal 3, a vitamin D concentrate, nicotinic acid, choline chloride, vitamin B₁₂, procaine penicillin, minerals 3.25 and yellow maize meal to 100; this ration contains only 4 per cent. crude fibre. Rations of this type gave as rapid growth and more efficient feed conversion than those of similar protein and vitamin content but with more fibrous grains and wheat milling by-products replacing part of the maize meal. Under the commercial conditions at the time of the trials it was economic to use the high-energy type through the whole 12-week period of rearing.

In trials with laying hens normal rates of egg production were obtained with high-energy rations, and feed consumption was approximately 10 per cent. less than with rations incorporating 30 to 35 per cent. of milling by-products and containing altogether 6 to 7 per cent. of crude fibre. Another advantage with birds kept on deep litter was that the lower feed consumption of the high-energy birds was accompanied by lower water consumption and less difficulty with damp litter.—K. J. Carpenter.

5920

FINDRIK, M. and CEK, A. Djelovanje lucernina brašna na rast pilića. [Effect of lucerne (alfalfa) meal upon growth of chickens.] *Vet. Arhiv*, 1955, **25**, 97-102. English and German summaries.

Alfalfa meal at a level of from 10 to 25 per cent. in the ration of young chickens, replacing an equivalent amount of wheat bran, depressed feed intake, growth rate and feed utilisation. At a

level of 5 per cent. growth rate was slightly depressed but feed efficiency was increased. (From summary.)—J. S. Thomson.

5921

LEME DA ROCHA, G. and RAIMO, H. F. Contribuição para o estudo dos substitutos dos farelos de trigo na alimentação das aves. 3. Mucuna preta. 4. Caupi. [Substitutes for wheat bran in the rations of birds. 3. Velvet bean. 4. Cowpea.] *Bol. Indúst. animal, São Paulo*, 1954, 14, 31-44. English summary.

Groups of 45 day-old chickens were used. The basal ration contained 35 per cent. wheat bran and middlings, replaced in the experimental rations by 35 per cent. velvet bean meal or cowpea meal. The experiment had 2 periods, from hatching to 14 weeks and from 14 weeks to 7 months of age.

The velvet bean meal was unsuitable for young chickens; growth was very poor and 46 per cent. died in 6 weeks, so the group was abandoned. Cowpea meal was as valuable for growth as wheat bran; the experimental group had 90-21 per cent. of the liveweight of controls after 14 weeks, but utilisation of their ration had been better. There was no difference in feathering. From 14 to 30 weeks the cowpea group gained 16.5 g. less than controls, and they started to lay on the average 5 days later and produced 2-15 per cent. fewer eggs.

It is concluded that cowpea meal is suitable for replacing wheat bran in poultry rations.

5922

SNYDER, E. S., PEPPER, W. F., SLINGER, S. J. and ORR, H. L. The value of pasture in the production of goose broilers. *Poultry Sci.*, 1955, 34, 35-38. [Dept. Poultry Husb., Ontario Agric. Coll., Guelph.]

White Chinese × Emden goslings were fattened from 3 to 14 weeks old. They received a pelleted ration, grain and water to appetite. Half the birds were reared on pasture, the other half in dry lot. They were weighed at 6, 9, 12 and 14 weeks and slaughtered at 14 weeks. The goslings reared without pasture were significantly heavier at all ages, their dressing percentages were 10 per cent. higher, and they gave more attractive carcasses than those reared on pasture. Those reared on pasture required less feed per lb. gain, and of the feed consumed about one-half was grain; when no pasture was allowed the ratio of pellets to grain was 40:1. Satisfactory geese as broilers killed at 14 weeks of age could therefore be produced by either method, but the more economical one was rearing on pasture.

T. D. Bell.

5923

ROSENBERG, M. M. Response of chicks to graded concentrations of cane final molasses. *Poultry Sci.*, 1955, 34, 133-140. [Dept. Poultry Husb., Univ. Hawaii, Honolulu.]

Three trials are reported on the effect on growth and feed efficiency of substituting different amounts of blackstrap molasses for part of the yellow maize in a ration of Napier meal, maize, soya bean oil meal and herring meal with mineral and vitamin supplements.

In the first experiment levels of 11.5, 23.0 and 34.5 per cent. molasses were used for groups of day-old chickens for 42 days, all rations being nearly equal in protein content. The 2 lowest levels did not depress growth rate. At the highest level the males grew significantly slower than their controls and the females at about the same rate as their controls.

Experiments 2 and 3 were similar on a slightly modified ration, except that 3 additional levels of molasses were tried, namely, 7.5, 16.5 and 28.5 per cent. When the results of these 2 trials were combined it was found that, apart from some group differences in rate of growth of pullets and cockerels, growth rate in all the molasses groups was as good as in the controls.

Efficiency of feed conversion was reduced significantly as the level of molasses rose but at the prevailing prices of feedingstuffs the molasses rations were cheaper than the control.

It is concluded that molasses can be included in the chick ration up to 34.5 per cent. but the optimum level would appear to be between 7.5 and 23 per cent. At the highest level tried the ration became too moist, and there was an increase of moisture in the faeces as the level of molasses rose.—J. S. Thomson.

5924

THAYER, R. H. and HELLER, V. G. Antibiotics and nitrogen utilization in growing cockerels. *Poultry Sci.*, 1955, 34, 97-102. [Oklahoma Agric. Exp. Stat., Stillwater.]

A group of 50 chicks was reared from hatching to 33 days of age on a ration of soya bean oilmeal 45, wheat protein hydrolysate 1, DL-methionine 0.24, soya bean oil 2.5, minerals, vitamins and glucose to 100. A second group received the same ration supplemented with 20 mg. of procaine penicillin G per lb. The mean finishing weights of the groups were 452 and 489 g.

At the end of the group feeding trial 5 cockerels from each group were housed for a 4-day experimental period in individual metabolism cages and continued to receive their previous diet. Of the nitrogen in the 2 rations, 14.2 and 13.9 per cent. were excreted as true protein in the faeces; 40.7

and 36.8 per cent. of the absorbed dietary N was excreted as urinary N.

From these and similar results with a practical ration given with and without the addition of penicillin or aureomycin it is concluded that antibiotic supplements can improve the utilisation of dietary protein by poultry.—K. J. Carpenter.

5925

LIBBY, D. A. and SCHAEBLE, P. J. Observations on growth responses to antibiotics and arsonic acids in poultry feeds. *Science*, 1955, **121**, 733-734. [Dept. Poultry Husb., Michigan State Coll., East Lansing.]

Successive batches of chicks were reared to 6 weeks of age in the same house over a 4-year period. In the first year birds that received either a low-level antibiotic supplement or a supplement of arsonic acids grew 19 and 16 per cent. faster than those that received the control ration without a supplement. This effect decreased until in the last year the mean growth stimulation obtained with these supplements was only 3 per cent. in each case.

However, over this period, and with the same strain of birds, growth on the control ration alone improved by 19 per cent., so that the final growth rate without antibiotics or arsonic acids was equal to that previously obtained only with these supplements. Mortality rates with the control ration also fell from 8.5 to 2.8 per cent.

It is concluded, therefore, that the failure to obtain a significant response to growth stimulants is not due to the development of alimentary tract bacteria that are resistant to their influence, but rather to the continued use of antibiotics in the building so as to eliminate those micro-organisms that had previously been responsible for depressing the growth rate of the chicks.—K. J. Carpenter.

5926

McDONALD, M. W. A failure of chickens to respond to arsanilic acid. *Poultry Sci.*, 1955, **34**, 55-56. [Poultry Exp. Stat., Seven Hills, N.S.W.]

Contrary to the results of Bird (*Feed Age*, 1952, **2**, 80), growth in chickens was not stimulated by the addition of 4.5 g. arsanilic acid per 100 lb. mash. The addition of 160 mg. procaine penicillin per 100 lb. of the same mash produced a significant increase in growth rate, but there was no further stimulation when arsanilic acid also was added.

J. S. Thomson.

5927

BAILLON, S. L. The effect of quaternary ammonium derivatives in chick diets. *Poultry Sci.*, 1955, **34**, 191-196. [Dept. Poultry Husb., Iowa State Coll., Ames.]

A series of 7 experiments is reported in which 4 alkyl quaternary ammonium derivatives were given to groups of young chickens on adequate diets, with or without antibiotics and housed in old or new quarters.

The quaternary ammonium derivatives consistently improved growth to 8 weeks in chickens housed in old quarters but had no effect on those in new quarters. Feed efficiency was significantly improved in both environments. The best results were obtained when the derivatives were given at a low level, 30 to 35 mg. per lb. feed, during early growth and at a higher level, 75 to 150 mg. per lb. feed, during the later stages. The addition of 2 per cent. fat to the ration improved feed utilisation still further.—J. S. Thomson.

5928

WRIGHT, M. M. and DUDLEY, F. J. A comparison of the effects of pellet and mash diets of similar composition on the productivity of Khaki Campbell ducks to the end of their fourth laying season. *Poultry Sci.*, 1955, **34**, 474-483. [Nat. Inst. Poultry Husb., Newport, Shropshire.]

In a series of trials Khaki Campbell ducklings were reared from hatchlings in 1946, 1947 and 1948 in houses with access to grass runs. They were fed to appetite on commercial feeds of unknown but similar composition with from 17 to 19 per cent. crude protein. The feeds were as mash or in pellet form and the mash was mixed with water to a crumbly consistency. At first feeding was frequent but after 9 weeks of age the ducks got only 2 feeds daily. There were 240, 146 and 99 birds in the groups for the years.

Birds on pellets drank much more water than did those on mash and their rates of feathering and of general development were more rapid. At 20 weeks their mean liveweight was about 5.2 lb. with only small differences between the groups. In nearly all birds feed consumption was highest in the period 8 to 12 weeks of age.

At 20 weeks groups of 40 ducks were selected at random from the hatches for laying trials over 4 years. Feed consumption was from 594 to 605 and from 591 to 615 lb. per duck for the pellet and mash groups, respectively, and their egg yields from 582 to 653 and from 599 to 632. In each comparison the differences between the forms of feed were inconclusive. Laying was most intense during April, May and June and did not cease entirely at any time of the year. The birds which laid heavily in the first 2 years seemed unable to continue thereafter at the same rate. Mortality was not significantly different in the groups and, for all birds over the whole period, was 41 per cent. More than one-third was caused by reproductive disorders.

The ducks would not have repaid the cost of their food in the third and fourth years and, in some cases, keeping them for a second year might have been uneconomic.—K. J. Carpenter.

5929

LANSON, R. K. and SMYTH, J. R. **Pellets vs. mash plus pellets vs. mash for broiler feeding.** *Poultry Sci.*, 1955, **34**, 234-235. [Dept. Poultry Husb., Univ. Maine, Orono.]

White Plymouth Rock male chicks were fed on mash for 4 weeks, then group 1 had the mash in pellet form, group 2 had one-third in pellet form and the rest as mash, and group 3 continued to get mash only. They were fattened to 10 weeks of age and then killed. Group 1 was best and group 3 worst in final liveweight and efficiency of feed conversion. Mortality was low and there was no feather picking in any group.—T. D. Bell.

5930

MCCALLY, E. H. and SPICKNALL, N. H. **Meat yield from live, dressed, and eviscerated Rhode Island Red chickens during growth and at maturity.** *Poultry Sci.*, 1955, **34**, 145-148. [U.S. Dept. Agric., Agric. Res. Serv., Animal and Poultry Husb. Res. Branch.]

The liveweight, dressed weight, eviscerated weight with giblets and weight of edible meat of 125 Rhode Island Red pullets, 85 cocks and 30 hens were measured, and relations between them were calculated. The liveweights ranged from 1134 to 3628 g., pullets being 10 to 16 weeks old, and hens and cocks 38 weeks old. Regression equations were computed. The most accurate calculation could be made between values involving the least treatment of carcass in dressing; thus weight of edible meat was best calculated from eviscerated weight. There was little difference between the classes of birds, and one equation could be used for them all. A table is given showing the calculated dressed yield of birds from 2.5 to 8.0 lb. liveweight.—T. D. Bell.

EGG PRODUCTION

5932

ERIKSSON, S. **Energy requirement for maintenance of adult hens.** *Kgl. Landbrukshögsk. Ann.*, 1954, **21**, 385-388. [Nat. Animal Exp. Stat., Uppsala.]

Vol. 25, No. 4

Non-laying Rhode Island Red hens weighing 2 kg. required 160 Cal. metabolisable energy daily at 20° C. (68° F.). The requirement was 12 per cent. greater at 15° C. (59° F.), but in the experiment reported the hens were beginning to moult when the observations at the lower temperature were made, so that the results need confirmation.

5933

HEYWANG, B. W., BIRD, H. R. and VAVICH, M. G. **The level of protein in the diet of laying White Leghorns during hot weather.** *Poultry Sci.*, 1955, **34**, 148-152. [Agric. Res. Serv., U.S. Dept. Agric., Animal and Poultry Husb. Res. Branch, Glendale, Ariz.]

Groups of 25 White Leghorn pullets were housed in an indoor pen with straw litter and given either all-mash ration 1 of sardine meal 4, commercial casein 1, lucerne meal 5, butyl fermentation solubles 0.3, cod liver oil 0.3, minerals 6.5 and yellow maize meal to 100, which contained 11.5 per cent. crude protein; or rations 2 to 6 which were of similar composition with higher levels of sardine meal and casein, in a 4:1 ratio, so as to give 12, 13, 15.5, 17, 18 and 19.1 per cent. crude protein.

The trial continued for 112 days of hot weather with daily average maximum and mean temperatures of 102° and 88° F. The egg outputs per head in the 6 groups were 37, 55, 55, 45, 54 and 56, and there was no appreciable change in liveweight in any group.

In a second trial which began with 153 days of relatively cool weather, daily maximum and mean temperatures being 72° and 59° F., mean productions on rations 1 to 6 were 69, 74, 91, 77, 78 and 82, and in a second period of 120 days of hot weather 50, 49, 50, 60, 54, 56 and 60.

It is concluded that a 15 per cent. level of crude protein is satisfactory in a laying ration of the type employed where it is to be given during hot weather.—K. J. Carpenter.

5934

NEAL, W. M. **Supplemental methionine for breeding hens.** *Poultry Sci.*, 1955, **34**, 242-243. [Route 6, Box 970, Tampa 4, Fla.]

In a series of field trials DL-methionine was added at a level of 0.05 per cent. of the total feed to the rations of laying birds receiving good practical diets of mash plus grains.

It was concluded that this supplement had the effect of reducing the proportion of eggs that were unsuitable for incubation because of their poor shell texture. It was suggested that the inadequacy of the rations without this supplement might have been due to the high temperatures at the time and the presence of some ascarid infestation and non-specific enteritis.—K. J. Carpenter.

5935

CARVER, D. S., RICE, E. E., GRAY, R. E. and MONE, P. E. The effect of No. 2 tallow in poultry rations on the flavor of fresh and stored eggs. *Poultry Sci.*, 1955, **34**, 131-132. [Res. Labs., Swift and Co., Chicago, Ill.]

Flavour of fresh eggs or of eggs stored for 1 or 2 months from hens fed for 11 days on a ration containing 3 per cent. of No. 2 tallow was not impaired.—J. S. Thomson.

5936

MACINTYRE, T. M. and JENKINS, M. H. Effect of different feeding methods on the efficiency of egg production. *Poultry Sci.*, 1955, **34**, 376-383. [Canada Exp. Farm, Nappan, N.S.]

Ten groups, each of 20 Barred Plymouth Rock pullets housed in an indoor pen with 6 in. feeding space per bird, were fed for 280 days on a laying mash, provided to appetite in their hoppers and made up of fishmeal 2, meatmeal 1, powdered milk 1, soya bean oilmeal 8, maize gluten meal 3, wheat middlings 7, wheat bran 6, wheat shorts 11, hominy feed 5, yellow maize meal 5, rolled wheat 10, rolled barley 10, crushed oats 22, cereal grass 3.5, minerals 5 and fish oil 0.5. In addition, a scratch grain feed was given daily in a quantity equal to that of the mash consumed, consisting of whole wheat 40, oats 25, cracked yellow maize 15, whole barley 10 and buckwheat 10. These birds had a 9.5 per cent. mortality, and laid 164 eggs per hen housed, with a mean weight of 62 g.

Similar groups of birds received 3 further treatments. They all received scratch grain and, in addition, had (1) a wet mash feed placed on top of the dry mash at noon each day; (2) laying mash to appetite and laying pellets distributed over the litter at noon or (3) laying pellets fed to appetite in the hopper with no mash. Mortality rates with these treatments were 10.5, 8.5 and 15.0 per cent. There was no appreciable difference in the total weight of eggs produced.

In further similar trials, all-mash feeding, either to appetite or provided in 4 feeds daily, gave results similar to those obtained with scratch grain and mash. However, inferior results were obtained when both grain and mash were provided to appetite in separate hoppers. The provision of pellets, for an evening scratch feed, that were made up of grassmeal 25, hominy feed 25, dried distiller's solubles 10 and middlings to 100 failed to increase the egg production of birds receiving an all-mash ration to appetite in their hoppers.

SIZEMORE, J. R., LILLIE, R. J., BIRD, H. R. and DENTON, C. A. Further studies on the influence of aureomycin in the chick diet upon subsequent reproductive performance of laying

hens. *Poultry Sci.*, 1955, **34**, 432-435. [U.S. Dept. Agric., Agric. Res. Serv., Animal and Poultry Husb. Res. Branch.]

In a previous paper (Abst. 1368, Vol. 24) the authors reported the findings of a trial in which birds reared on a ration supplemented with a vitamin B₁₂ and antibiotic concentrate subsequently gave eggs with better hatchability than eggs laid by birds receiving the same breeding ration but reared without the vitamin B₁₂ antibiotic supplement.

They now report the results from a second laying year in which the former group still gave generally better hatchability than the latter, even when the comparison was made with a breeding ration containing aureomycin. The difference appeared to be the result of a higher embryonic mortality in eggs from the latter group after the first week of incubation. There was also a tendency for the inclusion of aureomycin in the breeding ration to reduce embryonic mortality in both groups of birds.—K. J. Carpenter.

OLSSON, N. and KYRNING, S. Försök med grönfoderensilage i hönsens utfodring. [Silage as a feed for laying hens.] *Kgl. Lantbruks-högsk. Statens Hushållsförsök Medd.* No. 56, 1954, pp. 22. English summary.

A preliminary account of experiments in 1949 was published in *Proc. 9th World's Poultry Congr.*, 1951, **2**, 153. The 1949 results are reproduced here with those for 1950 and 1951.

The experimental groups were of purebred or hybrid Leghorns, 31 to 43 hens and 4 cocks per group, 6 to 8 months old at the beginning. The silage was of clover and grass in 1949 and of lucerne, second cut, in the later years, made with 3 kg. molasses and 3 litres water per 100 kg. green crop. Records were kept of egg yield and weight, hatchability, content of carotenoids and vitamin A and colour density of the yolk; feed consumption and liveweight and health of the fowls. The ration was a conventional mixture of cereals with yellow maize or haymeal or both, oilseed meal, fishmeal, dried milk, yeast, bonemeal, chalk, salt and charcoal. Methods of analysis are described and results are presented in detail. The silage groups had approximately 30 g. (range 26 to 33 g.) daily or silage to appetite with 0.42 per cent. cod liver oil in the mash. The latter group of hybrid birds in 1951 ate only 16 g. daily.

N.A. and B., October 1955

There was no difference in weight or health between the groups. The supply of precursors of vitamin A in the several combinations of silage with haymeal and/or yellow maize was adequate. There was no difference in fertility or hatchability. Groups that got vitamin A had more vitamin A in eggs than the others, which had eggs with more carotenoids and a deeper yolk colour. There was a slight excess of feed per kg. egg in the silage groups.—I. Leitch.

5940

HEYWANG, B. W., BIRD, H. R. and ALTSCHUL, A. M. Relationship between discolorations in eggs and dietary free gossypol supplied by different cottonseed products. *Poultry Sci.*, 1955, **34**, 81-90. [Agric. Res. Serv., U.S. Dept. Agric., Animal and Poultry Husb. Res. Branch, Glendale, Ariz.]

Groups of 10 to 12 White Leghorn pullets were fed on diets containing free gossypol at 0.001, 0.002, 0.003, 0.004, 0.005 and 0.008 per cent. which were variously provided by raw decorticated cottonseed, or screw-press, hydraulic, solvent-extracted or pre-press solvent-extracted cottonseed meal. The yolks of more than 1900 of their fresh eggs and of more than 13,000 of their eggs held in commercial cold storage at 35° F. for periods up to 6 months, or in a refrigerator at 55° F. for periods up to 7 days, were examined for discolouration.

At the 0.001 per cent. level of free gossypol only 1 fresh egg had a discoloured yolk, but 5 per cent. of all the yolks held in storage were discoloured. At the 0.008 per cent. level of free gossypol the figures were 16 and 60 per cent. discoloured yolks. The effects of gossypol from solvent-extracted meals were less severe than from other sources.

5942

CHARETTE, L. A. and TESSIER, J. L. Snow as a water replacement for poultry. *Canad. J.*

Agric. Sci., 1955, **35**, 175-180. [Exp. Stat., Kapuskasing, Ont.]

Barred Plymouth Rock pullets were used in laying trials in the winters of 1948-49, 1950-51 and 1951-52, in which birds got the same rations, and were housed in the same conditions, but got either drinking water warmed to 35° to 45° F. or snow. The trials, dependent on the availability of snow, lasted 112, 158 and 161 days in the 3 years during which they were made. Snow in place of water did not cause significant difference in egg size, total feed consumed, or mortality. The number of eggs laid was significantly greater when the birds had access to water, and efficiency of feed utilisation was higher. Weight increases were also better when water was given.—T. D. Bell.

5943

CARSON, J. R. and BRALL, G. Absence of response by breeder hens to ultraviolet energy. *Poultry Sci.*, 1955, **34**, 256-262. [Dept. Poultry Sci., Storrs Agric. Exp. Stat., Univ. Connecticut.]

Barred Columbian and Rhode Island Red laying hens were used in 2 year's trials in which the control groups were given 14 hr. daily incandescent light, and experimental groups had, in addition, 14 hr. daily antirachitic ultraviolet irradiation, continuous germicidal ultraviolet irradiation or both. The results showed that the treatments had no significant effect on egg production, egg weight, shell thickness, hatchability or mortality of adult birds.—T. D. Bell.

5944

VAN ALBADA, M. On the significance of some characteristics of egg production in breeding utility breeds of poultry. *Netherlands J. Agric. Sci.*, 1955, **3**, 135-154. [State Poultry Inst., Beekbergen, Netherlands.]

Trials with White Leghorns from 1947 to 1952 showed that more accurate selection could be based on average length of laying cycle and age at first egg than on total production for the first laying year. To apply this method, careful observations must be made for a few months while the birds are trap-nested.—T. D. Bell.

OTHER BIRDS

5945

JUKES, H. G., HILL, D. C. and BRANION, H. D. Effect of penicillin on the growth of pheasants. *Poultry Sci.*, 1955, **34**, 235-236. [Dept. Nutrit., Ontario Agric. Coll., Guelph.]

A group of 13 pheasants was kept in a darkened room and fed from hatching to 4 weeks of age on a

ration of fishmeal 2.5, meatmeal 2, dried butter-milk 2, soya bean oilmeal 42, grassmeal 5, minerals 5.25, fish oil 0.5, yellow maize meal 16 and ground wheat to 100 with supplements of methionine, riboflavin, nicotinic acid and vitamin B₁₂. They finished with a mean weight of 160 g. A parallel group that received the same ration supplemented

with 10 p.p.m. of procaine penicillin G finished with a mean weight of 173 g.

It is concluded that this result provides further

evidence that pheasants respond to antibiotics in the same way as chickens and turkey poults.

K. J. Carpenter.

FOOD ECONOMICS AND STATISTICS

5946

WYLLIE, J. The production of human food in the United Kingdom before, during, and since the war. *Empire J. Exp. Agric.*, 1954, 22, 241-255. [Wye Coll., Univ. London.]

This study covers the period of 11 years from 1939-40 to 1949-50, with 1936-39 as pre-war comparison. Official statistics of agricultural output in the United Kingdom are translated into calories, and fluctuations in output of the principal products and in their percentage contributions to total calories are given in tables. In 1939-40 crops contributed about 47 per cent. and livestock about 53 per cent. of total calories; in 1943-44, 71 and 29 and in 1949-50, 59 and 41, respectively. Milk and eggs contributed 30.2, 19.4 and 28.1 per cent. and meat 22.6, 9.4 and 13.2 per cent. Taking the yearly requirement per head as 1 million Cal., home production sufficed to feed 17.3, 26.3 and 23.8 million people and the acres required per person were 1.78, 1.15 and 1.28. The means by which production was increased are discussed and it is pointed out that *inter alia* mechanisation set free about 1 million acres formerly required to maintain farm horses. The same total calorie output can be achieved from different combinations of crops and livestock products; the diet provided by home production in 1949-50 was superior in "quality" to that of 1943-44 but the cost of 1 million Cal. was about £35 compared with £21 in the earlier year. In 1949-50 the approximate cost (i.e., price received by producer) of 1 million Cal. from wheat was £8, potatoes and sugar beet £13, meat £67, milk £44 and eggs £212.

W. M. Deans.

5947

LINDSTROM, D. E. Japan needs U.S. surplus food. *J. Farm Econ.*, 1955, 37, 125-127. [Rural Welfare Res. Inst., Internat. Christian Univ.]

In order to get more food for less cost, Japan is now importing much more wheat than rice, 46 million bushels against 24 million bushels in 1953. All political parties are agreed on the need for importing more wheat and inducing the people to change their eating habits. At present they consume on the average about 5 bushels per person per year, about 435 million bushels, but home production amounts to only about 330 million bushels. In view of the rapidly growing population and the unlikelihood of rapid increase in home production of cereals other than rice or of

milk and meat, the opportunity for the American farmer is obvious.—W. M. Deans.

5948

TEIXEIRA E SILVA, H. M. Tecnologia da produção e valor dos alimentos protéicos de origem animal. [Technology of production and value of protein feeds of animal origin.] *Bol. Indúst. animal, São Paulo*, 1954, 14, 134-140. English summary.

The value of animal by-products is discussed, including meatmeal and other slaughterhouse and cannery wastes, fish wastes and dairy products such as whey. It is concluded that large quantities of such substances are at present wasted in Brazil because of lack of facilities for processing them, and that installation of plant would soon give profitable returns.—D. Duncan.

5949

HAVEY, C. B. Economic aspects of hog production in North Dakota. *N. Dakota Agric. Exp. Stat. Bull.* No. 391, June 1954, pp. 39.

A survey was made of the south-eastern area of North Dakota. Half the farms in the area kept pigs and 78 per cent. of these kept breeding sows or gilts, and 71 per cent. of the latter group had 4 or fewer breeding sows. The majority bred for one farrowing only per year.

The survey showed that production efficiency, as returns per hour of labour or per unit of capital invested, increased sharply as the number of sows increased from 4 to 12, and less rapidly thereafter. The economic security of larger breeding herds was greater. There was a certain amount of risk in expanding the small enterprise, but this was usually profitable provided that it did not interfere with or reduce the scope of other enterprises on the farm. If expansion should cause interference then economic details should be carefully examined.

For efficiency and profit careful management in feeding and care at farrowing, in which there is room for improvement, are essential, especially in small enterprises. The seasonal market fluctuations in the price of fat pigs should be watched, and it should be decided whether current prices for feeds sold to the market would bring in less than the returns from pigs fattened on the feeds.

5950

BEYNON, V. H. Home-grown or purchased feedingstuffs? The choice before the farmer. *Agriculture, J. Minist. Agric. Engl.*, 1955, **62**, 1-6. [Dept. Econ., Univ. Bristol.]

To be profitable, homegrown feedingstuffs must not only cost less than purchased concentrates: the saving must also compensate for any loss incurred by using the land in this way instead of for some more profitable enterprise. A simple method of budgeting to show the relative profit is described, with examples. These show that even on understocked farms dredge corn is of doubtful advantage, but kale is usually profitable and grass silage may be.—T. D. Bell.

5951

SWANSON, E. R. Solving minimum-cost feed mix problems. *J. Farm Econ.*, 1955, **37**, 135-139. [Univ. Illinois.]

The use of the University of Illinois electronic computer for solving the problems which arise in finding the minimum cost of mixtures to provide particular levels of certain nutrients is described. D. Harvey.

5952

SHOLTO DOUGLAS, J. W. E. H. Soilless cultivation of crops in India. *Nature*, 1955, **175**, 884-885. [Hydroponic Res., Minist. Food, India.]

The system of soil-less cultivation which has been evolved at the Bengal Government's station at Kalimpong is briefly described and some very high yields obtained with tomatoes, lettuce, maize, French beans, rice, potatoes, onion, beetroot and broad beans are quoted. An information centre on the method has its address at P.O. Box 31, Bombay, India.—D. Harvey.

5953

PAYNE, W. J. A., NAIDU, R. K., SILLS, V. E. and HOLMES, S. V. Fish farming. *Fiji Agric. J.*, 1954, **25**, 71-76.

Animal protein for pig feeding is in short supply in Fiji. To improve the position a successful attempt is being made to grow the fish *Tilapia mossambica* in a pond excavated near the piggeries of the Sigatoka Agricultural Station. The pond was planted with an aquatic plant, *Ipomoea reptans*, which has grown rapidly and abundantly, and the fish were imported as fingerlings from Malaya. They grew rapidly and reproduced after 2 months. The pond water, which must be kept stagnant, is manured from the sump of the piggery. *Ipomoea* can also be harvested; providing human food from the succulent green tips, and a readily eaten stockfeed from the rest of the plant. The possibility of *Tilapia* as a food for man is also being investigated, and shows promise. The cultivation of *Tilapia* in Malaya, and the limitations imposed by local conditions in Fiji, are described and discussed.—T. D. Bell.

DIET IN ETIOLOGY OF DISEASE

GENERAL

5956

VAN DER GRIFT, J. Doel en werkwijze van de veterinaire verkenning van het Rijkslandbouwproefstation te Hoorn. [Functions of the veterinary field service of the Agricultural Research Station at Hoorn.] *Landbouwk. Tijdschr.*, 1954, **66**, 740-746. [Physiol. Rijkslandbouwproefstat., Hoorn.]

The English service of Veterinary Investigation Officers served as the pattern.

A study in 1952 of blood Cu in relation to pasture diarrhoea on 100 farms is reported. In each herd 3 to 6 samples were taken, depending on the size of herd and in 51 per cent. of these serum Cu was low, less than 0.60 mg. per litre blood; in 14 per cent. the results were between 0.60 and 0.70 mg.

Vol. 26, No. 4

and in 35 per cent. Cu was normal. The low samples were got from cattle pastured on heath, clay or peat, low moor and river clay soils. Pasture diarrhoea was severe in 1952 and, in almost every case, was cured or prevented by CuSO_4 . The fall of blood Cu which occurs on pasture was much less in the dry autumn of 1953 and health and milk yield were better.

Other current investigations are concerned with the possible association of haemoglobinuria with lack of Na and the effect of brackish drinking water on cattle.—I. Leitch.

5957

JOHNS, A. T. Bloat in cattle on red clover. 1. *N.Z. J. Sci. Technol. [A]*, 1954, **36**, 289-320. [Grasslands Div., D.S.I.R., Palmerston North.]

Bloat was produced in 2 pairs of stall-fed identical twins and one cow by feeding cut broad red clover grown in pure swards. Many possible causes were examined to determine their relation to the incidence of bloat in the experimental animals and most of the common statements of causes, such as the rate of eating, or the weather, have been found to be false. Certain things have been shown: (1) belching occurs in bloating cows, but may be suppressed in severely bloated animals; (2) the bloat produced was of the frothy type and punctures of the rumen, or even opening the rumen widely *post mortem*, did not allow sufficient gas to escape to make much difference; (3) anti-foaming agents never failed to protect animals; and (4) certain animals are prone to bloat.

In general it is concluded that both a plant factor, about which several suggestions are made, and an animal factor are concerned.

A review.

5960

PUNTRIANO, G. O. Further research on the prevention of kidney stones in sheep from the colloidal approach. *Amer. J. Vet. Res.*, 1955, 16, 101-104. [Wyoming State Vet. Lab., Laramie.]

For earlier work in which the concept is defined see Abst. 3990, Vol. 24.

Three groups of 6 lambs, 7 to 9 months old, were given a ration of concentrates containing 50 per cent. beet pulp, and alfalfa hay. Such a diet was believed to cause urinary calculi. This treatment lasted 5 months. One group was implanted with hyaluronidase. A fourth group, as control, got only alfalfa hay. In the 2 groups getting concentrates but no hyaluronidase urine examinations

gave evidence of the formation of calculi in the kidneys, but in the other groups there was no such evidence. There was also imbalance of the protective colloid: crystalloid ratio in these same lambs. Analysis of the calculi showed silica in amounts from 60 to 75 per cent. This was thought to be the cause of the calculi, the excess of silicate either increasing the proportion of crystalloids or forming silic [silicic] acid and increasing the proportion of non-protective colloids; in either case imbalance of the colloid: crystalloid ratio would result. The acid would also form a gel and act as a nucleus for the formation of calculi.—T. D. Bell.

5961

ALEXANDER, G., McCANCE, I. and WATSON, R. H. Some observations on losses among Merino lambs. Age at death, birth weight and duration of gestation of the lambs from one flock. *Austral. Vet. J.*, 1955, 31, 85-90. [Div. Animal Health Prod., C.S.I.R.O., Parkville, Victoria.]

Details of deaths of single lambs in a flock of Merino sheep are reported. Of a total of 421 lambs, 25 were stillborn, 13 died within 3 days and 13 died between 7 and 28 days. There were 21 males and 4 females in the stillborn, but among the other 26 the sexes were evenly distributed. Birthweights of the stillborn were significantly more and of those dying after birth significantly less than those of surviving lambs. Gestation periods did not differ significantly between the groups except for females which died between 7 and 28 days, for which they were longer.—T. D. Bell.

5963

COLES, R. The economic significance of the incidence of mortality in fowl. *Brit. Vet. J.*, 1955, 111, 235-252. [Minist. Agric. Fish. Food.]

Over 4000 birds were involved in observations made on the mortality of a flock of White Leghorns during 4 consecutive seasons of 78 weeks. During this time there was no culling. Mortality fell from 30 per cent. in the first to 14 per cent. in the fourth season, and just under half the deaths were due to

N.A. and R., October 1955

avian leucosis and fowl paralysis. Most deaths occurred between 11 and 36 weeks of age, when more were due to leucosis and fowl paralysis than to other causes. The mortality of late hatched (May) birds was less than of early (February to March), but the late hatched were older when they started to lay, so that fewer eggs were produced per bird in a season, offsetting the advantage of greater numbers of birds. The economic significance of the period of highest mortality and the breeding of resistance to leucosis are discussed.

STRAUCH, D. and BRÜNNER, F. Weitere Untersuchungen zur Frage der Mitwirkung des Mineralstoffmangels bei Störungen der Fruchtbarkeit der Rinder. [Further studies on the part played by deficiency of minerals in disturbances of fertility in cattle.] *Berl. Münch. tierärztl. Wochenschr.*, 1955, 68, 160-163. [Vet. Hyg. Inst., Justus Liebig Hochschule, Giessen.] English summary.

Three herds in Württemberg were studied; in each there was difficulty in getting the cows in calf, and in 2 the cows had non-specific vaginitis. The soil and homegrown fodder were somewhat low in P, but in 2 of the herds the P intake was apparently adequate, the diets containing 0.54 and 0.49 per cent. phosphoric acid. The herds were divided into 3 groups and given for 2 months no treatment, or a mixture of CaCO_3 and phosphate at the rate of 120 g. daily, or a trace element solution containing Mn, Co, Cu, Zn and I added to the concentrates.

At the end of treatment the vaginitis had cleared up in 12 out of 14 affected cows given Ca and P, 9 out of 13 given trace elements and 2 out of 12 untreated. Five out of 5 cows not pregnant at the beginning were in calf after treatment with Ca and P and 5 out of 6 treated with trace elements, but neither of the 2 untreated sterile animals bred.

SHANKS, P. L. and DONALD, L. G. An unusual mouth condition in sheep. *Vet. Rec.*, 1955, 67, 312-313. [N. Scotland Coll. Agric., Aberdeen.]

The condition reported consisted in nervous excitability and inability to close the mouth, with resultant loss of weight and emaciation through inability to eat. All the lambs of a flock grazing hill pasture were affected more or less severely. All but the 3 worst recovered when given bonemeal and injections of vitamins A and D. Consideration of the soils and fertilising programmes of the pastures indicated that the cause of the condition was gross deficiency of Ca and P. Reseeded pastures should not be used for growing stock, in which the Ca and P requirements are high, and if this cannot be avoided, extra supplements of bonemeal should be given.—T. D. Bell.

5968

MANN, I. A mobile bone meal factory to counter phosphorus deficiency in African livestock. *Colonial Plant Animal Prod.*, 1954, 4, 275-292. [Dept. Vet. Serv., Kenya Colony.]

Pasture analyses and the replies received to a questionnaire addressed to veterinary workers support the conclusion that throughout Kenya deficiency of P is a condition limiting production. The equipment described, mounted on a 3-ton lorry and trailer, has been designed to deal with bones at the rate of 3 tons a day and, under careful European supervision, to provide a product completely sterile for feeding to stock. The capital cost excluding the price of the lorry is £2250, and it is estimated that bonemeal might be sold to African farmers at about £11 per ton; the price current in Nairobi is £18.—D. Harvey.

5969

BENNETTS, H. W. Copper and cobalt deficiency of livestock in Western Australia. *J. Agric. W. Austral.*, 1955, 4, 43-63. [Animal Health and Nutrit. Labs.]

The distribution of Cu and Co deficiencies in Western Australia is described. There is some seasonal fluctuation in the severity of signs of deficiency. Cu deficiency in cattle produces retarded growth and unthriftiness of young stock, limb abnormalities, diarrhoea and anaemia. Unthriftiness, anaemia and diarrhoea occur also in adult cattle, and suppression of oestrus is common. Cattle eat soil. In severely deficient areas "falling disease" used to occur, but it has now been eliminated. Sheep have stringy wool, anaemia and diarrhoea, and lambs have ataxia. Foals in the Gingin and Dandaragan districts used to have limb abnormalities, now prevented by stable-feeding the mares.

Besides the serious Co deficiencies in the Denmark district and in the "coast disease" areas, there is widespread occurrence of less severe deficiency within about 15 miles of the coast.

The quantities of Cu and Co needed by different classes of stock and the best ways of supplying them are discussed.—D. Duncan.

BARBER, R. S., BRAUDE, R. and MITCHELL, K. G. **Studies on anaemia in pigs. 1. The provision of iron by intramuscular injection.** *Vet. Rec.*, 1955, **67**, 348-349. [Nat. Inst. Res. Dairying, Univ. Reading.]

Anaemia, as indicated by Hb level, was prevented by a single intramuscular injection of 2 ml. of an iron-dextran complex containing 50 mg. Fe per ml. The injection was given on the seventh day of life. The result was comparable to that obtained in a control group getting 30 mg. Fe as pyrophosphate in solution by mouth daily from the 7th to the 14th day. Another type of intramuscular injection of Fe, a suspension of phosphate, had no effect, and results with this were the same as with untreated controls, which became seriously anaemic.—T. D. Bell.

5971

BROWNLEE, W. M. **The treatment of piglet anaemia.** *Vet. Rec.*, 1955, **67**, 350-354. [Res. Dept., Vet. Sci. Div., Boots Pure Drug Co., Ltd., Thurgarton, Notts.]

Hb was estimated and total Fe in circulating Hb was calculated in baby pigs which had been made anaemic by being housed in conditions preventing access to Fe and being given a diet low in Fe. Some piglets were treated with a suspension of iron phosphate, or with an iron-dextran complex, both by an intramuscular injection supplying 100 mg. Fe. Others received by mouth a single dose of 500 mg. reduced Fe, and others remained as untreated controls. The injection of Fe as phosphate provided no Fe for Hb formation. Oral administration of reduced Fe gave a utilisation of 5 per cent., and the Fe in the form of iron-dextran complex was used to the extent of 85 per cent. in 9 days. In practice, one injection might cure anaemia but a second after 10 days would be advantageous if the pigs' appetite were poor. The creep feed should have a high Fe content.

TUCKER, H. F. and SALMON, W. D. **Parakeratosis or zinc deficiency disease in the pig.** *Proc. Soc. Exp. Biol. Med.*, 1955, **88**, 613-616. [Dept. Animal Husb., Agric. Exp. Stat., Alabama Polytech. Inst., Auburn.]

Pigs with severe dermatitis grew slowly and had diarrhoea, vomiting and anorexia; in extreme

cases they lost weight and died. Calcium pantothenate, nicotinic acid, pyridoxine, inositol, biotin, folic acid, vitamin B₁₂, choline, ascorbic acid, vitamins A, D, E and K, antibiotics, methionine, lysine and tryptophan in different combinations neither cured nor prevented the disease. In experiments with minerals the incidence and severity of the dermatitis were increased significantly by addition of 2 per cent. bonemeal or 1.5 per cent. CaCO₃ to the basal ration, but a mixture of trace elements effectively prevented its appearance. In further tests MnSO₄ alone had no effect, but addition of ZnCO₃ to the ration promptly cured the disease. The parakeratosis (dermatitis) syndrome occurred in pigs on basal rations containing 34 to 44 p.p.m. Zn and was cured by a supplement of 0.02 per cent. ZnCO₃. This indicated that in the pig the Zn requirement is relatively high.

A brief semi-popular account is given of milk fever, acetonaemia and tetany, including grass tetany. Just before the war there were 7 or 8

N.A. and R., October 1955

thousand cases of milk fever annually in Norway. With more pasture as feed and lower milk yields, the incidence fell to half that during the war. It has since risen greatly, to 6 times the 1945 incidence in 1950. On the other hand, acetonuria increased greatly during the war and fell after it, to rise again recently. Tetany also has increased recently and mortality was 14 or 15 per cent. in 1951.

All these disorders are attributed to disturbance of adrenal function, with complications, *e.g.*, of parathyroid in milk fever, of pituitary in milk fever and in acetonuria, which may be induced by underfeeding. The extension of grass tetany may be related to overmanuring with K relative to Ca and Mg.

General advice is given on feeding, with special emphasis on adequate feeding but not over-feeding during the dry period. Boda and Cole (*Hoard's Dairyman*, 10 January 1954) are quoted as having no milk fever in their herd and attributing their freedom to a low-Ca ration of green oats and barley with large supplements of P for 30 days before calving. The Ca:P ratio was about 1:3. Recommended Norwegian rations all have more Ca than P, and under Norwegian conditions a ratio of 1:3 would require very large supplements of P. A ration of timothy hay, timothy silage, straw and wheat bran would have almost equal amounts of Ca and P. The pros and cons of high-protein rations in the dry period are discussed. The conclusion is that the ration should be adequate in amount (Breirem's standard), appetising and balanced, with a supplement of P and of Cu and Co where necessary.—I. Leitch.

5977

LEWIS, E. F. Post-parturient metabolic disorders in the cow. An approach to therapy with special reference to prolonged recumbency. *Brit. Vet. J.*, 1955, 111, 253-257. [Dept. Med., Royal Vet. Coll., Streatley.]

Ideally, blood analysis should precede treatment for milk fever in dairy cows, since imbalance of Ca and P may be the cause rather than simple deficiency of Ca, but this is not always possible in practice. Magnesium should not be given unless there are clear indications of the need for it. Treatment with calcium borogluconate is described. Some cows will require more than others. Of 755 cases, 337 responded to one injection and only 12 showed inability to rise. The condition is often associated with other disorders, possibly resulting from mineral deficiency, such as degenerative muscle changes.—T. D. Bell.

5978

SEEKLES, L. and BOOGAERDT, J. Uitkomsten van een voederproef met magnesium-oxyde.

Vol. 25, No. 4

houdende voederkoekjes ter voorkoming van grastetanie. [Results of a feeding test with cattle cake with magnesium oxide to prevent grass tetany.] *Tijdschr. Diergeneesk.*, 1955, 80, 331-346. [Lab. Med. Vet. Chem., Rijks-univ., Utrecht.] English, French and German summaries.

An earlier paper reviewed the problems of grass tetany (Title 3797, Vol. 23). A large-scale experiment was begun in spring 1954 with the co-operation of veterinary officers. An analogy is thought to exist between grass tetany and "ordinary" intestinal disturbances because of common signs which are detailed. Grass tetany, or better "nutritional tetany", is regarded as a special form of "indigestion".

The speed with which the syndrome develops and the incidence on different soil types exclude the possibility that, in the Netherlands, an absolute deficiency of Mg could, in general, be the cause of grass tetany. Prevention, nevertheless, must be based on maintaining a normal level of Mg in blood. Means to that end might be (1) the administration of some substance which would affect the Mg regulating centre in the direction opposite to that of the poisons formed in the gastro-intestinal tract of high-producing cows; (2) avoidance of the excesses of current practice, by reducing the over-use of N and K fertilisers, or by rationing pasture or giving supplements of low-protein, high-fibre feeds such as beet pulp; (3) prevention of the fall of blood Mg by subcutaneous injection of large amounts, 30 to 50 g., of $MgCl_2$, or daily administration by mouth of a Mg salt to counteract the toxic effects of feed. Grass tetany will not be completely prevented by these measures as in Norway, where the tetany-paresis syndrome is due to absolute Mg deficiency, or in England in cattle pastured all the year round. The third treatment is that most likely to be put into practice.

The use is recommended of commercial or technical MgO , with safeguards regarding absence of poisonous metals and solubility in rumen fluid; it should be incorporated in amounts to supply 25 to 30 g. Mg daily.

The incidence of grass tetany is about 1 to 2 per cent. of the total dairy herd in a normal year, 1.9 per cent. in the province of South Holland where the pasture is most productive and most heavily stocked. Because the incidence is so low, herds were chosen there and in the province of Utrecht in which grass tetany was known to occur with an incidence of 6 to 8 per cent. In a total of 1426 cows in the control group only 17 had grass tetany in the spring of 1954 (60 expected) and in the lot of 976 given Mg-containing cake only 4. The difference was significant. A more extensive and more rigidly controlled experiment was to begin in the spring of 1955.—I. Leitch.

5979

O'MOORE, L. B. Tetany with fatal termination in ewes. *Irish Vet. J.*, 1955, 9, 95. [Biochem. Div., Vet. Res. Lab., Thorndale.]

An outbreak of tetany with low blood Mg is reported in a flock of 3-year-old ewes which had recently lambed and were grazing on 2- to 4-year-old leys. Convulsions were precipitated by any sudden excitement such as falling into a ditch or being driven through a gap. Analysis of serum of 15 ewes taken at random showed 11 with serum Mg values of 2.5 mg. per cent. and 4 with values of 1.4 mg. per cent.; 2 ewes in convulsions had values of 1.2 mg. per cent. Mg and 6.0 mg. per cent. Ca. Injection of a solution of Ca and Mg cured the condition. It is suggested that leys should be grazed alongside permanent pasture.

J. S. Thomson.

5980

POOK, H. L. Hypomagnesaemia in ewes. *Vet. Rec.*, 1955, 67, 281-282. [Salisbury.]

In a flock of Border Leicester \times Suffolk ewes running on downland ley pasture, 11 ewes died suddenly about 10 days after lambing twins. Death occurred after convulsions in a matter of 2 or 3 hr. Blood samples could not be obtained from affected ewes, but in 2-tooth ewes a week after lambing 3 out of 4 had serum Mg levels of 1.3 mg. per 100 ml. or less.

Mineral licks of high Mg content were given, but without effect, and Mg was not acceptable in trough feeds. One ewe found in convulsions recovered after 2 subcutaneous injections of Mg. Losses ceased when the ewes were removed from the first-year ley to a 4-year-old ley pasture.

D. Duncan.

5981

HALLGREN, W. Studies on parturient paresis in dairy cows. *Nord. Vet.-Med.*, 1955, 7, 433-463. [Res. Stat., Vet. Inst., Skara, Sweden.] German and Norwegian summaries.

In a district in the west of Sweden in 1951 to 1953 a veterinary surgeon treated 881 cows with diagnoses of parturient paresis. About 85 per cent. had typical milk fever and responded to Ca given intravenously. Of the other 15 per cent., 77 were examined by research station staff, and 12 of these were also diagnosed as milk fever in relapse; all recovered after more Ca. The others were a mixed lot, of which 9 had myocardial weakness. Many were unable to rise, but alert, and these usually had very low serum inorganic P and responded to intravenous P, usually as calcium hypophosphite. It is concluded that several other metabolic disorders can be confusingly like parturient paresis.

Another 481 fatal cases were obtained over the whole of Sweden, 212 in 1950-51 and 269 in 1953-1954. The diagnosis in all was clinical, without

chemical blood tests. Critical review suggested that in fact only 26.9 and 27.1 per cent., in the 2 separate years, were of true milk fever. Another 20.3 and 5.6 per cent. were down but alert and probably represented the low-P condition; the fall in mortality is attributed to better diagnosis. Liver and heart disease were the next in frequency when post-mortem diagnosis was considered.

The differential clinical diagnosis of parturient paresis is discussed. The Sulkowitch test for urine Ca is not of much value (see also Abst. 4571, Vol. 21). There was little correlation between urine Ca and blood Ca.—D. Duncan.

5982

MCCLYMONT, G. L. and SETCHELL, B. P. Ovine pregnancy toxæmia. 1. Tentative identification as a hypoglycaemic encephalopathy. *Austral. Vet. J.*, 1955, 31, 53-68. [Nutrit. Res. Lab., N.S.W. Dept. Agric., Vet. Res. Stat., Glenfield.]

Fasting for 4½ days caused pregnancy toxæmia in 13 of a group of 50 ewes which were 130 \pm 4 days pregnant. All the sick ewes carried twins. Blood sugar values during the fast reached significantly lower levels in the 13 ewes which developed pregnancy toxæmia, but in some returned to normal while signs of the disease persisted. High blood ketone values were not associated with the appearance of the signs. Pathological macroscopic changes in the liver, kidney and adrenal gland were not constant in sheep killed before natural death intervened, and these changes were considered secondary. The changes observed in nervous reaction were typical of cerebral depression due to low blood sugar and were similar to the signs induced by insulin hypoglycaemia. The induction of these signs depended on the severity of the hypoglycaemia and on its duration. If the nervous signs of pregnancy toxæmia are due to cerebral depression of this type, failure to respond to glucose or other treatment can be explained by the fact that the changes in the brain have reached a stage when they are irreversible.—T. D. Bell.

5983

LUDVIGSEN, J. Undersøgelser over den såkaldte "muskeldégeneration" hos svin. [Studies of so-called "muscle degeneration" in pigs.] [2. Nogle virkninger af jodkasein og metylthiouracil på stofskifteprocesserne, muskulaturen og skjoldbruskkirtlen hos unge voksende svin. [2. Some effects of iodinated casein and methylthiouracil on metabolism, musculature, and the thyroid gland in young growing pigs.] 3. Virkningen af jodkasein, tyroxin og diiodhistidin på tilvækst, foderforbrug, muskulatur, skjoldbruskkirtel og kødkvalitet. [3. The effect of iodinated casein, thyroxine and

N.A. and R., October 1955

diiodohistidine on growth, feed utilisation, musculature, the thyroid gland and pork quality.] *Forsøgslab. København Beretn.*, 1955, No. 278, pp. 59; No. 279, pp. 60. English and German summaries.

2. For Part 1, which outlines the nature and incidence of the disorder, see Abst. 1497, Vol. 25.

Literature on the effects of iodinated casein and thiouracil is reviewed and the suggestion is made that the discordant results with thiouracil may be explained on a breed basis, pigs with a high natural rate of growth showing much less effect than those with a low rate. It is further suggested that this depends on an association of high thyroid activity and slow growth. The pigs with which this report deals were not related to those described in Part 1.

The experiments with methylthiouracil and iodinated casein were repeated with 3 younger pigs of about 45 kg. liveweight, with a ration of cereals, soya bean meal, sour skimmed milk, minerals and "vitamin oil". The iodinated casein, 1.0 g. daily; arrested growth, i.e., weight increase, and was continued for only 14 days and methylthiouracil, 0.5 g. daily, was discontinued after 28 days when growth rate fell. Both were given again 14 days before slaughter. Balances of N, P and Ca were estimated over 14 days in each of the intervals with and without the drugs. Four control pigs were similarly treated. The results are presented in tables and graphs.

Retentions of N, P and Ca were above control levels in the pigs given thiouracil and below in those given iodinated casein. There was no difference in dry matter, total and protein N or soluble N in muscle, yet the animals given iodinated casein had "total muscular degeneration". This is in direct contradiction of the earlier findings with older pigs. An explanation in terms of blocking and stimulating the pituitary thyrotropic hormone is offered, which is thought to be supported by the finding that the thyroids of the pigs given iodinated casein were small and inactive, in those given thiouracil larger and more active than normal.

3. Further studies were made with 32 pigs from the same herd and closely related to those on which the first experiments were made, i.e., with a genetic predisposition to muscle degeneration. The ration was of cereals, skimmed milk, minerals and "vitamin oil". Some of the pigs were given a supplement of vitamin B₁ and pantothenic acid.

Many of the animals lost appetite and showed diarrhoea from time to time, without fever or any sign of infection, and with apathy and occasional death. These signs are thought to be part of the genetic syndrome. Muscle changes were advanced in the pigs that died, and the deaths are attributed to cardiac paralysis by the K of the effusions into

the heart muscle. There was hypertrophy of the adrenal cortex.

The curative effect of iodinated casein found in the first experiments was confirmed. Thyroxine in a large dose had no effect on the muscle; diiodohistidine had none on energy exchange but a slight effect on muscle, and it greatly increased thyroid weight. The effect of iodinated casein must be due to some other sub-product; it is not related to its effect on respiratory exchange and, in two preparations tested, that with little effect on energy exchange was by far the more active in curing muscle changes.

Hams from the pigs treated with iodinated casein, pickled, pasteurised at 76° C. and canned, were much superior in quality to those from control pigs with muscle degeneration.—I. Leitch.

POISONS OCCURRING IN FOOD

5984

HARVEY, J. M. and MOULE, G. R. Fluorosis of Merino sheep in Queensland. 3. The management of flocks to overcome fluorosis. *Queensland Agric. J.*, 1955, 80, 113-115.

For parts 1 and 2 see Abst. 4502, Vol. 25.

An experiment was made with 4 groups of 20 lambs, 3 months old at the outset. They were fed on poor quality grassy lucerne hay which they had to pull out of the bale. The experiment continued for 30 months. Group 1 had only water containing 10 p.p.m. fluoride for the whole period; group 2 had access to water containing 10 p.p.m. fluoride and water free from fluoride for alternating periods of 3 months; group 3 were similarly treated, but the alternating periods were of 6 months; group 4 had periods of 6 months on water containing 10 p.p.m. fluoride alternating with 3-month periods on fluoride-free water. These treatments were thought to simulate conditions arising in practice.

The teeth of sheep in group 1 were seriously affected, and large amounts of F were deposited in the bones. Group 3 suffered almost as much as group 1, and group 4 slightly less than group 3. There were only 3 sheep in group 2 which showed any sign of fluorosis.

The application of these findings to practical management is described. It is important not to let weanling lambs have access to water containing a large amount of fluoride for long periods. If no water free from fluoride is available, younger stock should be kept as near the source as possible so that they may have water which has not been concentrated by evaporation.—T. D. Bell.

5985

TESINK, J. De te nemen maatregelen bij chronische rundveefluorosis. [Measures to be taken in chronic fluorosis of cattle.] *Tijdschr.*

Diegenesek., 1955, 80, 299-308. [Kockeng-en.] English, French and German summaries.

For an earlier discussion of industrial fluorosis in Holland see Abst. 4503, Vol. 25.

Industrial fluorosis in a cow is described in detail. Where fluorosis occurs, cattle may not be bred. The factory is responsible for taking over all cattle and for replacing all immature cattle with others in which the dentition is complete. The herd shall be given cake in which Al_2O_3 is incorporated.

Methods are described for estimation of F in water, blood, urine, milk, feed and faeces, teeth and bone, horn and hair, soil, hay and grass.

I. Leitch.

5986

BUXTON, J. C. and ALLCROFT, R. **Industrial molybdenosis of grazing cattle.** *Vet. Rec.*, 1955, 67, 273-275; 276. [Vet. Invest. Lab., Sutton Bonington, Loughborough.]

Progressive emaciation and diarrhoea occurred in grazing cattle near an industrial town. The affected cattle were found to have blood Cu values of from 0.01 to 0.07 mg. per 100 ml. The conditions responded to treatment with $CuSO_4$ in the food or as a drench. Pasture samples contained, in p.p.m. dry matter, Cu 24 to 28, Mo 14 to 126 and F 4 to 12, and tree bark up to 250 p.p.m. Mo. Cows on one farm were excreting from 7 to 14 p.p.m. F in the urine after they had been housed for 2 months. Two animals had mottled incisors, but bone exostoses and lameness were not seen.

It was concluded that the condition was produced by aerial contamination of the pastures with Mo, and that it could be controlled by regular supplements of Cu.—D. Duncan.

5987

PARKER, W. H. and ROSE, T. H. **Molybdenum poisoning (teart) due to aerial contamination of pastures.** *Vet. Rec.*, 1955, 67, 276-279. [Vet. Invest. Dept., Wolverhampton.]

Scouring occurred in cattle on pastures in the English midlands near an aluminium alloy factory. The herbage contained from 25 to 50 p.p.m. Mo on one farm, and Cu treatment was quickly effective in curing the cows, which before treatment had blood Cu values as low as 0.02 mg. per 100 ml. On 2 other farms the blood Cu values and the response to Cu were similar. On a fourth farm, nearer the factory, pasture and trees were killed by contamination but the cows were in good condition; this pasture was subject to contamination with Cu and Zn as well as with Mo, and it was concluded that the Zn was responsible for the damaged herbage, and the Cu acted as antidote to the Mo.—D. Duncan.

5988

Tengkawang-schroot ongeschikt als veevoeder. [Tengkawang meal not suitable as cattle feed.] *Landbouwk. Tijdschr.*, 1955, 67, 216. [Rijks-landbouwproefstat., Hoorn.]

Tengkawang seeds are the seeds of species of *Shorea*, *Isoptera* and *Hopea* from which oil is expressed. The composition of the residue as cake or meal is shown. In a digestibility test 3 wethers given 600 g. meal and 600 g. grassmeal lost appetite within a day or two and one died with blood in the faeces and signs of severe poisoning. Since this might have been due to contamination, a second test was begun later with meal which did no harm to pigs as 40 per cent. of their ration. Wethers would not eat 600 g. and had slight diarrhoea; again one died suddenly. The percentage composition of the meal is: moisture 11.4, ash 5.1, crude protein 17.4, ether extract 1.4, crude fibre 10.2, N-free extract 54.5.—I. Leitch.

5989

COOKE, A. R. **The toxic constituent of *Indigofera endecaphylla*.** *Arch. Biochem. Biophys.*, 1955, 55, 114-120. [Hawaii Agric. Exp. Stat., Univ. Hawaii, Honolulu.]

The toxic principle of creeping indigo (*Indigofera endecaphylla*), one of the most promising legumes in the Hawaiian Islands, has been shown to be β -nitropropionic acid. In addition there is a fairly high nitrite content.—J. S. Thomson.

5990

PICKEN, J. C. (JR.), JACOBSON, N. L., ALLEN, R. S., BIESTER, H. E., BENNETT, P. C., MCKINNEY, L. L. and COWAN, J. C. **Toxicity of trichloroethylene-extracted soybean oil meal.** *J. Agric. Food Chem.*, 1955, 3, 420-424. [Iowa State Coll., Ames.]

The usual process of extracting soya beans with trichloroethylene was modified to encourage or impede auto-oxidative decomposition processes, the products of which were thought to be responsible for the toxicity of soya bean oilmeal extracted in this way. Trials with young calves showed that the modification introduced did not alter the toxicity.

Supplements of extracted soya bean oilmeal, soya protein and casein to which were added the products of auto-oxidation developed in the trichloroethylene extraction process did not cause any of the signs associated with poisoning by trichloroethylene-extracted soya bean oilmeal.

IMMUNITY

5993

RODABAUGH, D. E. and ELDER, C. **The effect of a low protein ration in hog cholera immunization.** *J. Amer. Vet. Med. Assoc.*, 1955, 126, 418-421. [Dept. Vet. Pathol., Sch. Vet. Med., Univ. Missouri, Columbia.]

In experiments in 4 consecutive years some sows were given a balanced ration and had access to bluegrass pasture, while others received a low-protein ration of ground yellow maize 95, linseed meal 5 parts and a mineral mixture and were kept on a plot of bare ground. The young pigs after weaning at 8 weeks were kept under the same conditions and were vaccinated with different products against hog cholera after 2 weeks, and 30 days later received a well-balanced fattening ration. Their immunity was challenged 45 or 90 days after vaccination by injection of fresh hog cholera virus, after which body temperatures were recorded daily for 2 weeks.

In pigs given antiserum and virus there was no significant difference between the diet groups and immunisation was effective. Modified virus vaccines either alone or with antiserum were less uniformly effective, but in 2 of the 3 years in which they were used clinical signs and deaths occurred only in pigs of the low-protein group. Even in this group most pigs showed nothing more than a transient rise in temperature.

It is concluded that the low protein intake was not solely responsible for failure of complete immunisation.—D. Duncan.

ÖBERG, G. and MELLANDER, O. **Antibody formation and nutrition. 2. Antibody titre in lambs and goats fed on homologous and heterologous milk using influenza and diphtheria vaccine as antigens.** *Acta Soc. Med. upsalien.*, 1955, 60, 14-16. [Hosp. Infect. Dis., Uppsala.]

For part 1 see Abst. 3807, Vol. 23.

Vol. 25, No. 4

2. The experiment reported in the earlier paper was repeated with 5 more pairs of twin lambs, with similar results. Ten goat kids were removed from their dams when 2 days old and bottle-fed with fresh cow's or goat's milk. At 8 to 14 days old they were inoculated with influenza A virus and antibody titre was measured up to 82 days afterwards. The mean value was always higher in the goats fed on goat's milk, though weight increases and general condition did not differ. With diphtheria vaccine both groups gave about the same antibody response.—D. Duncan.

5996

SPEDDING, C. R. W. **The effect of a sub-clinical worm-burden on the productivity of sheep.** *J. Brit. Grassland Soc.*, 1955, 10, 35-43. [Grassland Res. Inst., Hurley, Berks.]

From infested ewes worm-free lambs were reared by folding the lambs and ewes on to fresh pasture every third day. They never returned to the pasture once it was grazed. Another group of similar lambs was allowed to become infested by grazing on heavily infested pasture. This group and their ewes were then grazed on the pasture already grazed by the worm-free group. Over a period of 2 months, the worm-free lambs showed a faster rate of liveweight gain than the infested lambs.—G. C. Hunter.

GRUNSELL, C. S. **Seasonal variation in the blood and bone marrow of Scottish hill sheep.** *J. Comp. Pathol.*, 1955, 65, 93-107. [Dept. Vet. Hyg., Royal (Dick) Sch. Vet. Studies, Univ. Edinburgh.]

The relation of findings for blood and bone marrow to the helminths and nutritional state of Scottish hill sheep is discussed. Blood sampled in March and April had a lower red cell count than that taken in January, in early February and from May onwards. It is suggested that this is caused by the higher worm burden present in the sheep at that time of the year. There is a significant negative correlation between worm burden and packed cell volume in samples from January to early April. The absence of any association after mid-April is thought to be due to the improved nutrition of the sheep. The anaemia caused by *Trichostrongylus* spp. and *Ostertagia* spp. is not produced solely by blood loss.—G. C. Hunter.

7. BOOK REVIEWS

5999

HAMBIDGE, G. **The story of FAO.** D. Van Nostrand Co., Inc., New York and Toronto : Macmillan and Co., Ltd., London, 1955, pp. xii + 303. Price 48s. net.

After the Conference at Hot Springs in 1943 there was created an Interim Commission on Food and Agriculture. Its membership was representative of all the countries which had participated at Hot Springs and its task was the preparation of plans for a permanent food and agriculture organisation. Before it could be accepted the draft constitution which the Commission drew up required approval by at least 20 of the governments and, when that was given, the first Conference was called for 16 October 1945 in Quebec. There the Constitution was signed and on that date FAO came into being with a membership of 42 countries. All this and many of the results which have followed are told in this history of the Organization by its present North American Regional Representative, whose early associations with it were as Executive Secretary to its parental Interim Commission and later as its first Director of Information.

The pages tell graphically and often in American idiom of the conception, birth and growth of FAO and of its activities in the four main regions Near East and Africa, Far East, Latin America and Europe. For each area the system followed is to describe first the regional projects and then the investigations in the individual territories. Much of the narrative is at the level of high policy, but the 48 illustrations, whether of man or of beast, show the down-to-earth nature of the work. The direct words of one sentence in which are defined the Organization's aims in the field of extension work in the Near East in particular, might well be used in a wider context to describe a fundamental objective; "It must dig down into the village life and bring up native leaders who can be imbued with the aims and the philosophy of this great educational movement, now becoming world wide. It must, above all, seek the full understanding and co-operation of farmers and farm workers and their families."

The story is one of success told sometimes with picturesque detail and on occasion in dramatised form, with little mention of difficulties and frustrations being encountered in the receiving countries. The absence of such references from the narrative raises the interesting and by no means academic question whether technical assistance provided by an international organisation is regarded differently and with less suspicion than it would be were it

coming instead from some metropolitan government.

The high price of the book may limit to a significant extent its circulation in many countries outside the dollar area where its appeal might be greatest.—D. Harvey.

6000

BANKS, A. L. (Ed.) **The development of tropical and sub-tropical countries with particular reference to Africa.** Edward Arnold (Publishers), Ltd., London, 1954, pp. xvi + 217. Price 18s.

In July 1953 an informal seminar was held in Gonville and Caius College, Cambridge. It was attended by 32 persons of whom most were from university staffs, some were from international foundations and only one was a woman. The subject discussed at the 7 sessions spread over 4 days was, in the main, the impact on tropical areas of the progress in technology made in the temperate regions of the world. In particular the continent of Africa was in mind. It is the advance in one branch of technology, that of sound recording, that has made the form of this book possible and, after some editing of the transcriptions of records, the reader can now, in a sense, listen in to the discussions that took place. From a reader's point of view the result is interesting; from the reviewer's it is perplexing, since the magnitude of the problems discussed seems to match well with the vastness of the area in which they have arisen.

The proceedings began with a broad review of the problems inherent in the development of Africa and, in the second session, rose to a higher level when the objectives of technical development were considered. The sessions which followed were devoted to power and water, food and its production, health and welfare, and education. The final session took the form of statements of possible lines of action suggested, in order round the table, by 24 of the participants who imagined themselves faced with deciding what seemed to them individually the most desirable project. Whether those coming later in the circuit were influenced or not by the opinions of earlier speakers is impossible to decide, but the subjects placed first in order of precedence were almost as numerous as the proposers themselves.

It seems probable that all agreed on the complexity of the situations to which their differing proposals would give rise. There was, therefore, much wisdom in the suggestion made earlier that the political authorities in both parent states and

colonial countries should not remain ignorant of the changes occurring in the countries which they rule.—D. Harvey.

6001

HARRIS, L. J. **Vitamins in theory and practice.** Cambridge University Press, 1955, 4th ed., pp. xxii + 366. Price 35s.

The present edition is the fourth. The first three appeared in the short period from 1934 to 1938. The fourth comes after a much longer interval, and bringing the matter up to date must have been a very formidable undertaking. At first one regrets that there is no bibliography, only names and dates, but one quickly realises that to have given references would have enormously delayed the appearance of the book and would have greatly altered its character. Footnotes too are almost non-existent, and parentheses are not very numerous. The matter is thus properly digested into the narrative with the result that the story can be read with comfort and the thread never be lost, which in so intricate a tale is particularly important. Dr. Harris's great gift for lucid exposition ensures the reader's enjoyment.

The two opening chapters summarise the salient points in the history of vitamins and introduce the reader to the ever-growing number of them. Ten chapters are devoted to individual vitamins or small groups of vitamins, and the last is called "Dietetics—What to Eat". It is very clear and simple, and provides a lot of information valuable for the practical lay person. The book aims at being intelligible and of interest to the general reader, but it is intended also for science students, medical men and women and the like. It certainly should serve them exceedingly well. It is so clearly written that the great bulk of it should be comprehensible to the lay reader, and anyone who acquaints himself with the whole contents should have a very good general working knowledge of vitamins. It is a book that every vitamin worker will find himself referring to if he keeps it at hand.

It is not possible to comment fully on what has not been included, but one does feel that reference might have been made to the production of vitamin E deficiency and muscular dystrophy by cod liver oil. The adverse effect of cod liver oil is a practical problem in animal husbandry. It affects cattle, poultry and rabbits, and the lay mind will have somehow to digest the fact that the one-time panacea has changed, in certain connections, into a mischief-maker. Dr. Harris has with wisdom and tact sought throughout to promote a scientific outlook in his readers, and here is an example which the scientist could use to explain to the layman that very unwelcome and upsetting facts can come to light in the course of scientific discovery.

Vol. 25, No. 4

There is an index, but for a book of such wide scope it could have been more comprehensive.

E. M. Hume.

6002

BLADERGROEN, W. **Einführung in die Energetik und Kinetik biologischer Vorgänge. [Introduction to the energetics and kinetics of biological reactions.]** Wepf and Co., Verlag, Basle, 1955, pp. ix + 368.

The recognition that many aspects of the behaviour of organisms can be interpreted in terms of the properties of chemical reaction systems has emphasised the importance of the part that thermodynamics and kinetics can play in the development of biochemistry. In recent years a number of articles and reviews have dealt with aspects of this problem, but no systematic account has been available. This book is therefore to be welcomed. It is written at a relatively elementary level with adequate introductions to the fundamentals of both physical chemistry and biochemistry. The most satisfactory sections are those dealing with the concepts of thermodynamics and their application to biological problems. The chapters dealing with kinetics are less comprehensive, since the only type of kinetics considered in detail is that of enzymic reactions. The formal kinetics of reaction systems is not considered, although there are now a number of instances in which this has been applied successfully to biological reactions both *in vitro* and *in vivo*. The book is, however, successful in achieving an integration between biochemical and physico-chemical ideas and in outlining a field in which there are likely to be important developments in the future.—H. G. Bray.

6003

GLICK, D. (Ed.) **Methods of biochemical analysis.** Volume 2. Interscience Publishers, Inc., New York and London, 1955, pp. vi + 470. Price 75s.

The second volume of this series maintains the high standard set by the first. The analytical methods reviewed include those for steroids (infrared spectroscopy), adrenaline and *nor*adrenaline, lipids, lipoxidase, compounds with folic acid activity, vitamin E, coenzyme A, proteolytic enzymes, glutathione, serum glycoproteins and cytochrome *c* oxidase. Other sections deal with colour reactions for the determination of sugars in polysaccharides and with techniques for terminal and sequence studies of peptides and proteins. The methods considered are described in detail and a critical evaluation is made of their applicability.—H. G. Bray.

6004

KENT, P. W. and WHITEHOUSE, M. W. **Biochemistry of the aminosugars.** Butterworths Scientific

Publications, London, 1955, pp. ix + 311. [Dept. Biochem., Univ. Oxford.] Price 40s.

This appears to be the first extended account of amino-sugars and their derivatives to be published since Levene's monograph of 1925 and is therefore sure of a welcome among chemists and biochemists. The authors have collected their material assiduously and presented it in a clear and concise manner. The result is a textbook which will be of interest and value to students, teachers and research workers in many fields of chemistry and biochemistry. It must be said, however, that the title chosen for this book does not accurately indicate its scope. The authors state that their subject has been approached from a biochemical point of view and it is true that much of the background material is arranged and discussed from a biological standpoint. Only two chapters, however, are concerned with strictly biochemical information, namely, those dealing with the enzymic degradation of amino-carbohydrates and the metabolism of amino-sugars. It is clear from the length of these chapters that our knowledge of the role of amino-sugars in metabolism is still very meagre. The major, and more important, part of the book is chiefly concerned with the distribution, isolation and chemical behaviour of amino-sugars and related compounds and complexes. The section dealing with the chemistry of amino-sugars consists of chapters on the structure, properties and reactions of glucosamine, glycosides of glucosamine, galactosamine and 2-amino-hexonic acids. The book is well indexed and contains an extensive bibliography of all the topics treated.

H. G. Bray.

6005

PAECH, K. and TRACEY, M. V. (Eds.) *Moderne Methoden der Pflanzenanalyse*. Zweiter Band. Dritter Band. [Modern methods of plant analysis. Volumes 2 and 3.] Springer-Verlag, Berlin, 1955, pp. xii + 626, price 154s.; pp. xiii + 761, price 193s.

These two volumes form part of a four-volume work and follow a general account of up-to-date analytical methods which are applicable to plant materials. In their introduction the editors state that their "ambition . . . was to produce a laboratory manual of the highest standard possible". It can be said at once that they appear to have succeeded in their object extremely well. The different sections have been written by experts and, although the styles in which they write differ, all have produced accounts which will be of great value to the plant chemist and biochemist.

Particularly useful are the descriptions of the applications of chromatographic and ion-exchange techniques, which are becoming indispensable. Each review contains an extensive list of relevant references, so that these volumes will serve also

as an important bibliography. Volume 2 contains accounts of the estimation of mono- and oligo-saccharides and acidic monosaccharide derivatives, acyclic sugar alcohols, inositol and related compounds, ascorbic acid, phosphorylated sugars, starch, glycogen, fructosans and similar polysaccharides, cellulose and hemicelluloses, pectins, chitin, plant gums and mucilages, glycosides, fats and other lipids, volatile alcohols, aldehydes, ketones and esters, volatile acids, non-volatile mono-, di- and tri-carboxylic acids and lactones. Volume 3 is concerned with lower terpenes, pyrethrins and allied compounds, triterpenes and saponins, phytosterols, steroid saponins and cardiac glycosides, carotenoids, rubber and gutta, quinones, tropolones, simple benzene derivatives (phenols and acids), phenylpropane derivatives, lignans, anthocyanins, chalcones, aurins, flavones and related water-soluble plant pigments, lignin, natural tannins, anthraglycosides and dianthrone, growth substances in higher plants and antibiotics.—H. G. Bray.

6006

SCHARRE, K. *Biochemie der Spurenelemente*. [Biochemistry of trace elements.] Paul Parey, Berlin, 1955, pp. viii + 404. Price DM. 39.60.

This review consists of two main parts which deal with the role of 34 elements in soil and plants and of 24 elements in animal and human nutrition. Each section contains an extensive list of references which together occupy 130 of the 404 pages of the book, so that it will serve as an important bibliography.—H. G. Bray.

6007

DEUEL, H. J. (Jr.) *The lipids. Their chemistry and biochemistry*. Volume 2. *Biochemistry: Digestion, absorption, transport and storage*. Interscience Publishers, Inc., New York and London, 1955, pp. xxvi + 919. Price £10.

This book attempts to record and correlate all the available information concerning the digestion and absorption of lipids from the gastro-intestinal tract. Amongst the many topics covered are lipolytic enzymes, the role of bile, digestibility, pathways of absorption and methods used in the study of fat absorption. In addition to the full treatment accorded to triglycerides, an account of the fate of ingested phospholipids, waxes, sterols, hydrocarbons, carotenoids and fat-soluble vitamins is given. This section of the book is followed by an extensive description of blood lipids in normal and pathological states. The occurrence of lipids in the animal body as a whole is well covered and includes a detailed description of their distribution in specific tissues and their secretions.

As a work of reference the book is excellent, having an exhaustive subject index (over 50 pages)

and an author index. References in the body of the text are given in footnotes chapter by chapter.

G. A. Garton.

6008

RYTAND, D. A. and ANDERSON, J. (Ed.) **Annual review of medicine. Volume 6.** Annual Reviews, Inc., Stanford, Calif., 1955, pp. xiv + 459.

6009

MOUTIER, F. and CORNET, A. **Les gastrites. [Gastritis.]** Masson et Cie, 120, Boulevard Saint-Germain, Paris, 1955, pp. viii + 403. Price 4400 fr.

This text is largely a summary of the author's own work. Their experience in the diagnosis of gastritis in its different forms is described in detail with a wealth of illustrations reproduced both in black and white and in colour. From its nature the book must be of interest more to the clinician and the pathologist than to the nutritionist. The section devoted to treatment contains brief descriptions of the foods to be taken or to be avoided.—D. Harvey.

6010

HUTNER, S. H. and LWOFF, A. (Eds.) **Biochemistry and physiology of protozoa. Volume 2.** Academic Press, Inc., New York, 1955, pp. xiii + 388. Price 72s.

6011

SIMMONS, N. O. **Compound milling and associated subjects.** Leonard Hill, Ltd., London, 1955, pp. xix + 279. Price 42s.

Early in 1939 there was published "Provender Milling", by J. F. Lockwood, a member of a well known firm of milling engineers. In its two editions it has remained the standard text on the processing of feedingstuffs for livestock (see *Abst.* 2886, Vol. 15). Now a member of the same firm has prepared this book which deals more exclusively than did the earlier one with the machinery and gives less attention to the nutritional aspects of the subject. Descriptions have been assembled of all the varied types of machinery required for handling and treating the products between their arrival at the mill in their raw state and their leaving it in blended form ready for immediate

use. The result is a compilation which will be most valuable in countries where the manufacture of feedingstuffs is a growing industry.—D. Harvey.

6012

DANISH AGRICULTURAL ORGANISATIONS, COPENHAGEN. **Danish agriculture. Denmark as a food producer.** 1954, pp. 94.

This charming small book gives as good an account of Danish agriculture as has been written. It may be short, it may be quasi-popular, but the whole picture is there, historical and actual. Those who are accustomed to think of Denmark in terms of butter and eggs, cheese and bacon will be specially interested in the development of exports of breeding stock, meat, horses, seed potatoes, cereal seeds and fruit, especially apples. The book is illustrated with very good photographs and with marginal sketches, descriptive and comic or romantic.—I. Leitch.

6013

EWING, W. R. **Poultry nutrition.** W. Ray Ewing, Publ., Post Office Box 248, S. Pasadena, Calif., 1951, 4th ed., pp. xiv + 1518. Price 45.

This edition of a standard work is even more packed with information than its predecessors. The book mainly consists of a series of abstracts of many hundreds of papers classified under such headings as "protein", "fibre", "minerals", "slipped tendon". It is always clear what paper is being quoted, and contradictory opinions follow each other without comment, which is confusing until the principle is understood that the author is concerned to present first a guide to everything that has been said on each subject.

The short concluding chapters are of an entirely different nature and give clear practical advice on the designing of poultry rations, with comprehensive tables of the composition of feedingstuffs and the requirements of birds at different ages for individual vitamins and amino-acids so far as these are known.

With increased knowledge about the needs of turkeys, ducks and game birds the chapters dealing with these birds have been extended, and standards are given for the rates of growth and feed consumption that can be expected.

The 1500 pages of this book also include unexpected information, for instance on methods of sardine fishing on the Pacific coast (p. 259).

K. J. Carpenter.

8. FOOD AND AGRICULTURE ORGANIZATION (AND OTHER ORGANIZATIONS) OF THE UNITED NATIONS

Monthly Bulletin of Agricultural Economics and Statistics.

Vol. 4, No. 6, June 1955, pp. 40. Price \$0.50.
Vol. 4, No. 7, July 1955, pp. 48. Price \$0.50.
Vol. 4, No. 8, August 1955, pp. 60. Price \$0.50.

Yearbook of Food and Agricultural Statistics. 1954, Vol. 8, Part 1. Production. Rome, Italy, 1955. Price \$3.50. 1954, Vol. 8, Part 2. Trade. Rome, Italy, 1955. Price \$3.50.

Commodity Reports. Meat and livestock. Rome, Italy, July 1955, pp. 47. Price \$0.25.

Commodity Policy Studies No. 6. Uses of agricultural surpluses to finance economic development in under- developed countries. A pilot study in India. Rome, Italy, June 1955, pp. v + 65. Price \$1.00.

Of the 3 methods that might be employed to utilise surpluses (1) as an aid to economic development, (2) in welfare feeding programmes or (3) as relief in areas threatened by famine the first alone is dealt with in its applicability to India. The economic principles involved are fully considered so as to avoid interference with the economics of either the receiving or other exporting countries. The greater part of the study gives illustrative examples first of the distribution in kind of the surplus for use by those receiving it or by their families and second of additional employees being put to work on schemes of national importance and their extra requirements being met by the sale to them of the surplus products. Projects in the first group are mainly educational in nature; those in the second are concerned with road construction, irrigation works, re-forestation and prevention of soil erosion.

The need for other countries to work out similar development schemes with the present report as their model is stressed by the Director-General.

Commodity Policy Studies No. 7. The stabilization of the international trade in rice. A report on possible measures. Rome, Italy, August 1955, pp. iv + 38. Price \$0.50.

Report of the Council of FAO. Twenty-first Session, 6-18 June 1955. Rome, Italy, July 1955, pp. vi + 81.

The state of food and agriculture 1955. Review of a decade and outlook. Rome, Italy, September 1955, pp. xi + 236. Price \$2.50.

Since 1947 FAO has published annually a review of the state of food and agriculture. The 1955 edition is an enlarged one because the opportunity has been taken on the Organization's completing the first decade of its existence to include, in retrospect, a summary and, in

prospect, a long-term appraisal of developments and their effects. The recovery that has taken place in the post-war years and the progress in technology which has contributed so much to the increase in production are fully dealt with. Throughout the text there are many sets of data which allow comparisons of the pre- and post-war situations and the trends in the feeding of both man and animals are indicated. Nearly half of the book is devoted to a ten-year review of production, trade, prices and the short-term outlook for 19 commodities, 12 of which are foods or feedingstuffs.

Development Paper No. 52. Fact-finding with rural people. Rome, Italy, August 1955, pp. xii + 138. Price \$1.50.

This manual is intended both for the use of government officials and others whose duties may include the planning of social surveys and as a handbook of instruction for those who may have either to make the investigations or to interpret them. Suggestions for the selection of the facts to be investigated and for their analysis and presentation are amply dealt with and illuminating examples are given from actual experience in surveys made in different parts of the world. As the emphasis is on the social aspects dietary surveys receive no special consideration. There is a bibliography which runs to 33 pages and in which many of the studies have been grouped according to the regions in which they were made.

Report of the Third regional meeting on Food and Agricultural Programs and Outlook in Latin America. Buenos Aires, 1-10 September 1954. Rome, Italy, 1955, pp. 99. Price \$1.00.

The third regional meeting was attended by delegates from 17 Latin American, 1 North American and 3 European countries and by observers from 10 international and Inter- and Pan-American organisations. Basic agricultural problems and policies were considered and a number of recommendations were made with the aim of improving regional co-ordination and avoiding indiscriminate expansion of production which would accentuate the problem of surpluses. On the particular subject of the improvement of nutrition it was recommended that governments should determine for each region what is the minimum cost of a family diet and that this cost should be the basis for fixing wages. Specific problems on which recommendations also were made were technical assistance to farmers, livestock planning, statistics, marketing and plant protection; others were on related problems in the development of forestry and fisheries.

There are appendices (pp. 54-99) giving papers prepared for the meeting.

FAO Nutrition Meetings Report Series No. 9. Joint FAO/ WHO Expert Committee on Nutrition. Fourth report. Session held at Geneva 26 Oct.-2 Nov. 1954.

N.A. and R., October 1955

Rome, Italy, July 1955, pp. 58. Price \$0.60. Issued also as World Health Organization Technical Report Series No. 97.

At its fourth session the Joint Committee resumed consideration of the wider aspects of the subject as at its second session (see p. 1016, Vol. 21), the third having been limited to malnutrition in mothers and children (see p. 485, Vol. 24).

An outline is given of the separate and joint studies made by the Organizations since 1951. There follow under 12 headings more detailed references to particular subjects

on which advances have been made or on which further investigations are required. Suggestions towards such researches are advanced concerning requirements for energy and protein, the search for suitable protein-rich foods for infants and children, enrichment of dried skimmed milk with vitamins A and D, non-nutritive additives to foods, educational training in nutrition and in the particular diseases, pellagra, endemic goitre and degenerative conditions especially as they affect the heart. The use of anthropometric measurements for the assessment of nutritional status is also suggested for review.

See also Abst. 5999.

9. DEPARTMENTAL AND OTHER REPORTS

AUSTRALIA

Commonwealth Scientific and Industrial Research Organisation. 6th Annual Report for the Year ending 30th June 1954. Pp. 179.

Division of Biochemistry and General Nutrition

Nutrition and wool production. Causes underlying the seasonal variation in wool production by merino sheep: metabolic lesions occurring in copper deficiency; protein metabolism and wool growth.

Processes of rumination. Distribution of nitrogen between the protozoa and bacteria of rumen contents; digestion of nitrogenous compounds and conversion of plant nitrogen to microbial nitrogen; amino-acid composition of microbial protein; hemicellulose bacteria.

Carbohydrate metabolism of sheep. Pyruvate levels in blood; insulin hypoglycaemia; hexokinase activity of intestinal mucosa and brain; effect of pancreatotomy; toxicity of fluoroacetate.

Minor elements in animal nutrition. Cobalt deficiency in ruminants and relation to vitamin B₁₂; copper deficiency in sheep and relation to molybdenum.

Pinularis staggers.

Urea nitrogen as source of protein for sheep.

Metabolism in pregnant ewes. Pregnancy toxæmia.

Drought feeding of sheep.

CANADA

Range Experiment Station, Kamloops, B.C. Progress Report 1947-1953. Pp. 53.

Timber milk vetch (*Astragalus serotinus*) poisoning.

Abortion in beef cows caused by western yellow and lodgepole pine needles.

Cobalt and urea in relation to nutrition of sheep.

UNITED KINGDOM

Grassland Research Institute, Hurley, Berks. Experiments in Progress. No. 7, 1954 and 1955 Pp. viii + 72.

Production of worm-free lambs at pasture.

Worm infestation of sheep in relation to pasture management.

Vol. 26, No. 4

Lungworm infestation of cattle in relation to pasture management.

Feeding value to pigs of herbage leaf protein extracts.

Bioassay of leaf protein extract.

Automatic recording of grazing behaviour.

Studies on the intake of pasture by grazing animals.

Analysis of minerals in plant material (P, Fe, Al, Mn, Zn, Cu, Mo, Ni, Co).

Large-scale extraction of leaf protein.

Feeding value of herbage leaf protein in chick rations.

Biological value of leaf proteins by the Thomas-Mitchell method.

Distribution of organic nitrogen compounds in plants.

UNION OF SOUTH AFRICA

South African Institute for Medical Research. Annual Report for the Year ended 31st December 1954. Pp. 106.

Calcium metabolism in South African Bantu. Chemical composition and density of bone; incidence of rickets in urban and rural areas; the height-weight relationship in Bantu mine workers.

Iron metabolism in the Bantu. Correlation between serum iron and hepatic siderosis; maternal serum-iron, breast milk iron and infant hepatic iron concentrations; histopathology and iron concentration of vertebral bodies from Bantu adults habituated to a high iron intake; haemoglobin concentration and nutritional state; haemoglobin concentration in gross under-nutrition.

Diet, serum cholesterol concentration and atherosclerosis. The etiological role of dietary factors other than fat; pathological grading and chemical composition of aorta from elderly Bantu and European subjects; serum cholesterol in obese Bantu women.

Nutritional studies on Bantu babies and young children. Methionine concentration of Bantu breast milk; rarity of scurvy in Bantu infants and children; metabolism of nutrients by Bantu children suffering from kwashiorkor.

Parasitic disease and nutritional state.

UNITED STATES OF AMERICA

Sixty-seventh Annual Report of the New York State
College of Agriculture, 1954. Pp. 119.

Relation of feeding and management to cause of the "stiff-limb" disease.
Comparison of various protein supplements and supplemental mixtures, and effects of vitamin and antibiotic supplements for growing and fattening pigs.
Prolongation of productive life.
Protein requirements of growing, fattening lambs.
Nutritional requirements of herbivora as studied by purified diet methods.
Comparison of protein supplements for fattening lambs.
Comparison of certain concentrate feeds for milk production.
Physiology and metabolism of fats and related constituents in animals.
Effect of curing methods upon feeding value of hay.
Investigations with young dairy calves on effects of composition of dry starters, levels of starter and hay consumption, and rumen inoculation, levels of milk consumption, and antibiotics.
Requirements and functions of cobalt in rations of livestock.
Value of cull beans in rations for fattening lambs.
Study to determine most economical methods of fattening steers under New York conditions, using maximum amount of pasture and other roughage with minimum amount of grain.
Milk production from permanent and rotation pasture mixtures, and its relation to herbage characteristics.
Studies on causes and prevention of reproductive failures in dairy cattle.
Causes and prevention of ketosis in ruminants.
Development and use of indirect methods for measurement of digestibility and rate of consumption of feedstuffs, particularly forages, by ruminants.
Value of molasses and urea in rations for dairy cattle.
Influences of feeding and management practices of young upon early rumen development and subsequent mature performance.
Nutritional requirements of baby pigs.
Whole-body composition and carcass studies of cattle at different ages and at 3 nutritional levels.
Chemical and biological evaluation of nitrogenous requirements of animals.

Influence of antibiotics in rumen digestion and synthesis.
Development of dry diets for mink.
Value of fat (beef tallow) in the ration for fattening lambs.
Pantothenic acid requirements of poultry.
Folic acid requirements of poultry.
Requirements of poultry for vitamin B₁₂.
Requirement of poultry for compounds furnishing labile methyl groups.
Requirements of poultry for nicotinic acid.
Requirements of poultry for protein and amino-acids.
Studies of physiology of growth, development, production, and food utilisation by poultry.
Mineral requirements of poultry.

JAPAN

The National Institute of Nutrition, Tokyo. Annual
Report 1954. Pp. 63.

Effect of environmental temperature on basal metabolism of Japanese.
Effect of environmental temperature on calorie intake of Japanese.
Energy metabolism of physically handicapped persons.
Studies on basal metabolism related to menstrual cycle.
Calcium balance of middle school boys and girls.
Estimation of calcium requirement of Japanese people during growth.
Fortification of takuanzuke (pickles) with calcium, vitamin B₁ and vitamin B₂.
Effect of maturing on the vitamin C in vegetables.
Estimation of vitamin C in foods with 2,4-dinitrophenylhydrazine.
Stability of vitamin A in enriched miso (soya bean paste).
Stability of vitamin A during baking of enriched bread.
Availability of vitamin A and carotene to deficient rats.
Biochemical effects of vitamin B₁ and riboflavin derivatives.
Effect of vitamin B₁₂ and antibiotics on calcium and protein utilisation.
Effect of sugar on the influence of oxalic acid on calcium utilisation.
The diet of urban workers.
Absorption of calcium and phosphorus from rice.
Iron intake of Japanese.
Iron binding capacity of human blood serum.
Salt intake of Japanese.
